

Windows stores written text

Windows secretly stores your written text via the Handwriting Recognition tool which takes stylus or touchscreen inputs. <https://digit.in/oct18-46-1>

Training employees in VR

Walmart to use Oculus Go headsets to train its employees and give them instructions with simulation. <https://digit.in/oct18-46-2>

A reminder about pre-ordering

Agent001 takes a look at the new NVIDIA cards, and he isn't exactly overjoyed.

Agent001 | agent001@digit.in

O

h boy! NVIDIA's new Turing RTX 2080 and RTX 2080 Ti cards are ... not what they were all made up

to be. There's something amiss about a presentation when benchmark numbers are not showcased. Then again, most launches don't showcase benchmarks until the day of announcement so that when it does happen, the impact is maximised. Every major tech company does it. So, when NVIDIA was pulling the same old PR trick, no one felt that things were out of order. However, on the day of the announcement, the most expected element i.e. the benchmarks for the new graphics cards were missing. There was a ridiculously ambiguous excuse of a chart which indicated that the performance gap between Pascal and Turing based cards would be the same as the gap between the Maxwell and Pascal cards. So a 50 percent improvement in performance was expected, that too after two years. On top of that, consumers would be getting RTX (Real Time Ray-Tracing) and DLSS (Deep Learning Super Sampling) which are touted to be massive improvements in the graphics business.

However, when the date of the launch date was close, another thing was missing from the scene. The review samples! Even North American

reviewers did not get their samples up until two days prior to launch. What usually arrives 1-2 weeks ahead of launch came 1-2 days prior to launch. As a result, reviewers were not even able to test the cards properly but whatever they could test, was enough to showcase that the new cards did not match up with expectations. The RTX 2080 turned out to be practically the same as the GTX 1080 Ti and the RTX 2080 Ti only had a 30% lead in most

"But... but Agent001! What about RTX and DLSS? Why are you discounting these features?"

Frankly my dear gaming enthusiast, they're non-existent. None of the games out in the wild right now have implemented RTX and none have implemented DLSS. In theory, these are groundbreaking technologies in the world of graphics. RTX is basically an ancient tech that's been optimised to run in real-time and DLSS is going

Not up to expectations

benchmarks over the GTX 1080 Ti. So two years down the line and a completely new architecture later, we have in our hands one of the most underwhelming cards that I have ever seen. We know that Volta was awesome and if these RTX cards were made using Volta without all the fancy RTX and DLSS technologies, then we'd be looking at a pretty great gaming graphics card. Instead, we have in our hands a novelty token.

to do the same with anti-aliasing. Both technologies, in their current form are extremely intensive and with NVIDIA's spin on them, they are promised to make graphics appear super awesome and almost life-like. We've all seen the RTX Star Wars tech-demo. Having a graphics card capable of running that in your PC is a big deal. But where are the RTX games? And why on earth is DLSS not available. The former, I can understand. It's a
