

PROMISING BLOCKCHAIN STARTUPS IN INDIA

The blockchain startup scene in India might produce some amazing local and global solutions

Abhijit Dey | abhijit@digit.in

While several startups were heavily focused on cryptocurrency for the last few years, especially when the exchange rates skyrocketed, there were only a few who were building applications of its underlying technology – blockchain. Now that the government burst the crypto bubble, startups which were using this technology for different applications are surfacing, along with new ones also making an entrance. We had the opportunity to attend the International Blockchain Congress 2018 held at Hyderabad that claimed to be Asia's largest blockchain event. Out of the numerous blockchain startups from various sectors attending, here are our favourites.

BLOOCUBE

The pharmaceutical industry has a layered system of logistics that primarily covers drug manufacturing and supply. They also deal with clinical trials of the drugs at different levels ranging from animal to human testing to ensure their quality and effectiveness. While blockchain technology is already being explored for the supply chain segment by several companies and startups, clinical trial management is also something that can immensely take advantage of this technology. Bloocube is exploring this opportunity to streamline the

process of conducting clinical trials with new drugs. The system can be scaled and customised to cater to the required needs so that it can accommodate various diseases and conditions. Their system will take care of the complete process right from planning to implementation and even monitoring the finances. Using blockchain to handle the process improves the data accuracy, integrity and security of the system. Smart contracts can be further implemented in the system so that it becomes easier to implement automated deals when the drugs are deployed further from the trials.

DIRO

Identity verification has been known to be a popular application of blockchain technology. KYC verification is implemented to verify your identity for banks and legal documents. The usual process is to physically hand-over the documents or by uploading an electronically signed copy of the same documents. However, these methods are vulnerable to instances of false identities and identity thefts that can cause serious damage to the individual. Currently, your identity is scattered all over and there's no unified way to confirm whether it's you at all these places. Diro is trying to use blockchain technology to develop a decentralised identity and access platform. It will enable users to be easily verifiable and instantly enable KYC formalities. The system relies on a crowdsourced directory since shared contacts are a more trusted source for real identities. Eventually, this will form a verified profile that can be accessed by anyone to verify your identity. If this works out, you wouldn't have to manually go through the entire process of KYC before joining or subscribing to various services. Your identity will be accessible and verifiable via blockchain.
