

NANOHEALTH

Healthcare is a popular sector where blockchain technology can provide many advantages. Being a sensitive industry where people's lives are at stake, the patient's health records and diagnosis information are essential. Any kind of inaccuracy in data or data breaches can prove fatal for multiple people. Hence, the patient information hosted on a blockchain will be a great first step. Nanohealth is planning to leverage the same technology for their healthcare solution platform. Their services include an integrated platform where users can enter their medical history and ailments to serve as an electronic health record that can be shared with physicians or specialists. This will enable users to generate a health dashboard giving them details about diseases, colour-coded based on how risky they are. It will then serve personalised recommendations to book doctors or specialists. Physicians will also be able to look at health records so that they can monitor their patients and prescribe check-ups as required. An entire ecosystem of services from a single platform will essentially make healthcare more accessible and less of a hassle for both the sides.

SPATIUM

Hardware wallets tend to be more secure compared to software wallets since the user has to physically authenticate transactions every time. Spatium claims to have built an "ultra-secure" software and hardware wallet for cryptocurrencies. Each transaction usually requires a signing of public and private keys. In Spatium's protocol, private keys aren't generated at all so there's nothing to store to be compromised by hackers. This wallet will be able to store up to 100 cryptocurrencies together along with multiple signatures for teams using the same wallet. Users will also be able to sign a transaction without an internet connection using physical devices such as smartwatches, phones and the hardware wallet. The Spatium hardware wallet is the size of a credit card with a fingerprint scanner and NFC chip embedded in it. Users can use the card at Spatium-enabled point-of-sale ter-

minals for transactions in the future. An interesting feature in the hardware wallet is the Plausible Denial feature for security issues when users are being forced to make a transaction. By enabling it, a small number of funds can be pulled in temporarily while the rest of it is safely locked away.

STATWIG

Supply chain management can benefit from blockchain technology to a great extent. Not only will it enable quicker and secure logistics but it will massively reduce redundancies. The factors become more complicated when dealing with cold storage since they have to deal with food, vaccines and biological products. StaTwig is trying to solve this by implementing supply chain management over blockchain. An efficient cold chain is essential for the pharmaceutical industry since a majority of their business depends on storing and transporting products at the right temperature. Additionally, there are multiple middle-men participating between the source and destination. StaTwig will try to ensure the products can be tracked and traced easily while carrying out the delivery and storage. The process can be made more streamlined by implementing Smart Contracts at various points.

VERI DOC GLOBAL

Document fraud is pretty common since it's difficult to verify whether the document shared is the original one in the first place. There isn't any reference when a document is shared with an end-user for verification. Veri Doc Global seems to have solved this problem by leveraging blockchain technology. The way their authentication system works is quite simple. When an original document is created, it is stored on the blockchain. When the document is to be shared electronically, their system creates a unique QR

code which has a hash code embedded in it. This hash code is linked to the original copy stored on the blockchain. When the end-user wants to verify the document, they will scan the QR code. After scanning the QR code, the app will decrypt the hash code and present the original copy to them. Now, the end-user can verify whether the sent document is the same as the original copy or not. Veri Doc Global will definitely find itself useful in several sectors such as passport verification, driving licenses, bank statements, etc.

ZTIPS

Anonymous tips for crimes and information have been exchanged since forever. However, there's always a risk of compromising the leaker's identity. Also, there isn't much of an incentive from reporting crimes anonymously. ZTips wants to provide a decentralised and anonymous platform for crime reporting between information seekers and providers. They intend to collaborate with crime investigation agencies, financial institutions and media sources so that a unified platform can

be created. This will make it easier for tipsters to leave their valuable information anonymously while gaining incentives using tokens. These incentives or rewards are set between the providers and seekers. The exchange of information is bound by decentralised autonomous Smart Contracts so that none of the parties can back out of the deal. ZTips can prove to be a great platform for whistleblowers as well, without compromising on secrecy.
