

With 5G, videos will watch you

The 5G network will potentially reinvent the way we watch videos by making it a two-way interactive experience. <https://dgit.in/nov18-29-1>

Voice assistant in Honda Cars

Honda has partnered with SoundHound to speed up the development of its in-car AI companion. <https://dgit.in/nov18-29-2>

INSTALLING EMBER

Ember has its own command line build tool known as Ember CLI. It allows a lot of features that make Ember awesome. To install Ember using npm, simply type in the following:

```
npm install -g ember-cli
```

A small section of all the companies that use Ember

The installation should commence immediately. Once it is done, type in the following to verify the installation:

```
ember -v
```

BASIC CONCEPTS

Before we can go about building an app with Ember, we have to understand how an Ember application - and that will require the comprehension of some basic concepts.

Router and Route Handlers

Ember answers query about current state through URLs. Whenever a URL gets set or changes, Ember router maps the URL to a route handler. At this point, the route handler renders a template then loads an available model to the template.

Templates

Templates are Ember's way of organising HTML layouts in an application. They pretty much look like ordinary HTML code. For instance,

```
<div>Hi, this is a valid Ember template!</div>
```

Templates in Ember are also capable of displaying contextual properties.

```
<div>Hi {{name}}, this is a valid Ember template!</div>
```

Here, `{{name}}` is provided by the context of the template. Along with properties, the double curly brackets `{{}}` can also contain helpers and components.

Models

A persistent state in Ember is represented by a model. For instance, when an app wants to publish certain information, there would be a model that defines the structure of the information to be published. A model can be configured to store information anywhere.

Components

If templates were responsible for the looks part of the UI, components are responsible for the UI behaviour. It comprises of a template and a source file (written in JS).

Hooks

Methods that are called automatically within Ember are known as Hooks.

Some examples of a hook are:

- **Component Lifecycle Hooks:** the `willRender()` hook gets called before each time a component renders
 - **Route Hooks:** the `model()` hook is used to load the model on a route
- Enough explanations, let's get our hands dirty.

CREATE A NEW APPLICATION

If you've gotten the installation part right and verified the install as well, this where you create your first application. You will have access to a new ember command on your terminal thanks to the Ember CLI. The command to create a new application is ember new as in:

```
ember new ember-quickstart
```

Running this single command will create a new directory for your application and place the required files within it. Right from the beginning, you will get a few things with your application, like:

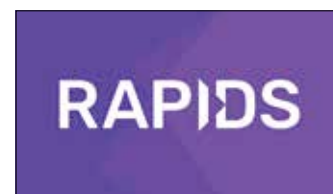

- A development server.
- Template compilation.
- JavaScript and CSS minification.
- ES2015 features via Babel.

*CODING MATTERS

*MongoDB changes license

MongoDB has changed its open source license type to prevent commercial organizations in Asia using the DB commercially without sticking to the open source rules. <https://dgit.in/MongoLic>

*RAPIDS GPU data analysis platform

A collection of software libraries for machine learning and data analysis has been released by NVIDIA. The GPU-based system, RAPIDS, consists of a suite of open-source software libraries for data science and analytics pipelines on GPU. <https://dgit.in/RapidsGPU>

*Github launches Actions

GitHub has launched a new tool called GitHub Actions that you can use to build, share and execute code directly on the site. It is to cut down on the steps to execute code.. <https://dgit.in/GitActions>
