Wear your health

The future of healthcare wearables is powered by some crazy ideas

Arnab Mukherjee | arnab@digit.in

A

t the recent Apple event, something interesting happened. For the first time in

years, a large chunk of people in the world of tech were of the opinion that the most exciting device launched was not an iPhone, iPad or Macbook - it was the Apple Watch Series 4. Packing features like blood pressure detection and fall detection, Apple upped its commitment towards making its only wearable device more health centric - something that the industry could use more of.

Almost every fitness tracker that comes out today releases with the basic set of step tracking, sleep tracking and other features extending on the same sensors used for these two. A select few come with blood pressure detection but the implementation quality remains questionable. With this in perspective, Apple's additions to the Apple Watch lineup makes this the perfect time to ask the wearable industry questions pertaining to the future of healthcare.

Certain concepts and prototypes have been doing the rounds which hold a lot of promise - or at least a brave idea. For starters, take Microsoft's Glabella. Designed as a pair of glasses, the wearable device is going to be equipped with a host of sensors that will passively gather physiological data on the wearer for further

analysis. The research paper where the company has detailed the device indicates that the design will have optical sensors as the primary detection mechanism. These sensors will use reflected light to measure the flow of blood and also take into account the inertial measurements of the user's head to avoid errors in the data. The Glabella glasses perform at par with traditional blood pressure measurement techniques.

The future of wearables for healthcare doesn't necessarily have to be device focussed. A California based company LifePlus has seemingly cracked a healthcare wearable problem that folks over at Cupertino

real time. With this, doctors will have unprecedented insight into patient behaviour without having to depend on patient responses. The same data when applied processed by machine learning algorithms, can even allow symptom tracking and disease detection that wouldn't be within the realms of human capabilities. Machines can pick up these clues well before there is a medical problem. Cardiogram's Deepheart uses data from the Apple Watch to detect hypertension, sleep apnea and has recently added diabetes, a non-heart condition, to the list. It could do so by analysing the heart rate data of a multitude of individuals, classified as diabetic and non

have been eyeing for ages - non-invasive glucose monitoring. Dubbed Lifeleaf, its first, and perhaps only, wearable offering combines multiple sensor readings to monitor blood glucose, heart rate, blood pressure, respiration rate and oxygen saturation - without any invasion. Then, using its software, the platform aims to monitor the user for diabetes, cardiac arrhythmia, congestive heart failure, sleep apnea and hypertension. The company also wants to make its platform open source, making its first wearable a reference product. It aims to guide the Garmins and Fitbits of the world to implementing its software in the best possible way.

The focus on software opens a lot of doors. Earlier this year, Fitbit announced plans to make user data available to doctors using Google Cloud in

diabetic. It has an 85 percent success rate which is significant for a wearable device.

All these devices and many more that we didn't have the space to talk about indicate two things about the future of wearables in healthcare - it will be ubiquitous and software will be as important as hardware in it. From smart shoes that will track your weight and gait and smart shirts that will transmit your physiology to your insurers, almost every single existing item in your wardrobe will get a wearable technology embedded into it - for your own good. All of this data will then be presented on a plate to artificial intelligence that will deliver insights at a detailed level to you, and if need be, to your physician. The future of healthcare is assisted and AI driven, thanks to wearables.
