

Widget Screensaver

Widget screensaver is a nifty little app that is able to turn any widget into the smartphone's screensaver. <https://dgit.in/jan19-45>

5G is 4G?

AT&T says that the 5G symbol at the top-right corner of this image is actually an advanced 4G network. <https://dgit.in/jan19-46>

The demo screen

get started with the next step which involves loading the screens.

LOADING FIRST SCREEN

Now that we have our prerequisites setup it's time to create something and check everything is working.

Create a file called index.html inside of the webroot (where the web server will look for the files to serve) and add the code at <https://dgit.in/PH2> into it.

WHAT DID THAT DO?

Open your web browser and load the index.html page up. Try typing in localhost/ or 127.0.0.1/ into your

browser. Sometimes you may need to specify a port number as well, it depends entirely on which server set-up method you used.

If everything goes right it will display the following demo in your browser.

DEEPIVE INTO PHASER:

A typical phaser file looks like the code at this link: <https://dgit.in/PH3>. Let us examine each of the components involved in the code.

The config object is how you configure your Phaser game. There are lots of options that can be used for configuration

and it is strongly recommended to go through each of them in detail in order to fully understand Phaser's capabilities. But in this tutorial we're just going to set the Renderer, Dimensions and a default Scene.

An instance of a Game object is assigned to a local variable called game and the configuration object is passed to it. This is what will create the Phaser game on our browser.

The type property can be either `Phaser.CANVAS`, `Phaser.WEBGL`, or `Phaser.AUTO`. The canvas element that Phaser creates will be simply be appended to the document at the point the script was called, but you can also specify a parent container in the game config should you wish.

Next, the width and height properties set the size of the canvas element that Phaser will create. In this case it is 800 x 600 pixels. The actual game world can be any size, but this is the resolution the game will display in. Let us now try to load the assets we need for our game. You do this by putting calls to the `Phaser.Loader` inside of a Scene function called `preload`. Phaser will automatically look for this function when it starts and load anything defined within it.

Let us update the preload function with code present at <https://dgit.in/PH4>. This will load in 5 assets: 4 images

*POINTERS

*Make your first Phaser game

Try this tutorial to build your first game with Phaser.io as an alternative to this particular tutorial. Send us your final game at editor@dgit.in. <https://dgit.in/Phasergame>

*Complete Mobile Game development course

Hands-on online course to learn iOS and Android Game Development from total scratch! Learn JavaScript, HTML5, Phaser and Cordova <https://dgit.in/PHZenva>

*Top Udemy Phaser courses

Learn Game Development from total scratch with JavaScript, HTML5 and Phaser with the top course on Udemy by Pablo Farias Navarro <https://dgit.in/UdemyPhaser>
