

Smartphone boom

India's smartphone shipments to reach 160 million next year, while Samsung and Xiaomi fight for top spot. <https://dgit.in/jan19-47>

Your own Canvas

Google launches web-doodling app called Google Canvas to turn your browser into your notepad or canvas. <https://dgit.in/jan19-48>

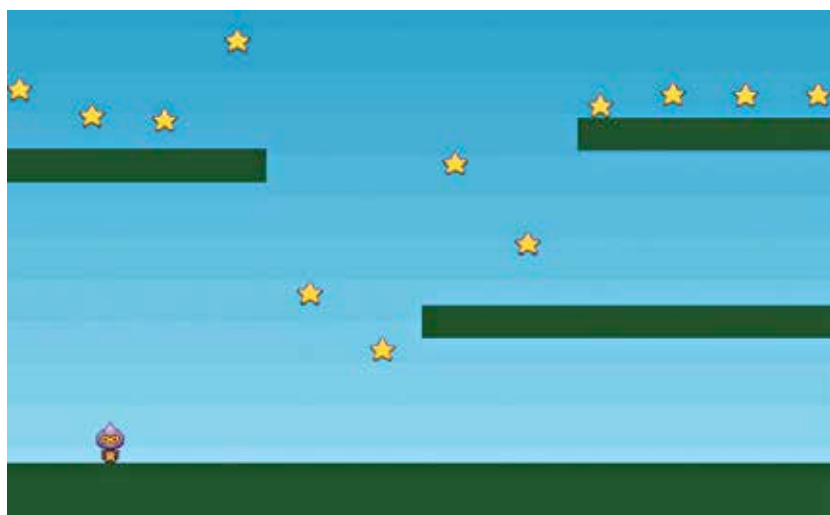

and a sprite sheet. Here, it is necessary to point out the first parameter, also known as the asset key (i.e. 'sky', 'bomb'). This string is a link to the loaded asset and is what you'll use in your code when creating Game Objects. Any valid javascript string can be considered an asset key.

Display an Image

In order to display one of the images we've loaded place the following code inside the create function:

```
this.add.image(400, 300, 'sky');
```

If you load it in a browser you should now see a game screen with a

The game screen

blue sky backdrop covering it. Please note that the order in which game objects are displayed matches the order in which they are created. So if you wish to place a star sprite above the background, you would need to ensure that it was added as an image second, after the sky image. Keep these instructions in mind and you should be looking at a screen that you intended throughout this project.

Next we look at loading a complete Scene using the update function as shown at <https://dgit.in/PH5>.

We can see that we have made a call to `this.physics`. This means that the Arcade Physics system is being used, but before we can do that we need to add it to our Game Config to tell Phaser our game requires it. So let's update

that to include physics support. In the config object make the changes shown at <https://dgit.in/PH6>.

READY PLAYER ONE

At this point we are ready for the next major step in our project and perhaps the most important one in the development of any game. Next we add our player to the platform. Let us create a new variable called player and add the code to the create function from <https://dgit.in/PH7>.

Next, let us add controls for the player. If this scares you, rest assured because there's a pre-built solution at

work here that's going to make your life easy. Phaser has a built-in Keyboard manager that is very easy and simple to use and can be done using the code at <https://dgit.in/PH8>.

The above code should be pretty readable, in essence we are moving the player and giving it velocities based on the keys pressed.

Finally, we can add a few other game elements like stars for the player to collect, thereby giving the game a purpose. Once we do that our game should look something like the image shown below!

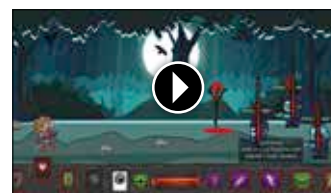

This is what the basic game looks and feels like when using Phaser.io. This is definitely not a complete game, however, it leaves room for you to experiment and build one! 

*VIDEOS

*Getting Started with Phaser 3.0

This video is a simple introduction and getting started tutorial, quickly covering a ton of topics. <https://dgit.in/GSPhaser>

*Game development using Phaser

A detailed and free course on game development using Phaser, divided up by step wise objectives. <https://dgit.in/PhaserCourse>

*Pros and Cons of Phaser and How it works

In this video, experts from Fullstack academy break down what makes Phaser work. They also analyse what's good and bad about it. <https://dgit.in/ProConPH>
