A quick guide to popular filming formats

The world of cinema needs no introduction. If you're reading this in January 2019, in the last month alone a lot has happened in the world of cinema with multiple movie trailers and announcements, some amazing movie releases and perhaps even the Academy Awards nominations are out. While many people go to the movies just for the sheer entertainment value, since their inception, a section of people have been interested in all the components that make a movie - the creative and the technical aspects. One such crucial aspect, that is subject to a lot of debate amongst cinema enthusiasts, is that of filming formats.

SERIOUSLY?

Yes, cinema geeks, we know you're looking at us with scepticism. The reason would definitely be the fact that it is impossible to cover all types of filming formats, analogue and digital across monochrome and colour in the span of two pages. This topic is worth a book and we know that because there are books that have actually done this. What we're trying to do here is provide a primer for the uninitiated to delve into the world of cinema formats. Maybe we'll have a full-fledged FastTrack on this someday. It was a breakthrough because it allowed cameramen to shoot a massive two and a half minute of footage from a single cartridge. As expected, it became the dominant choice for home video throughout the 70s and 80s. It was pretty easy to load as well, requiring less than two seconds to be loaded into a Super 8 camera without ever having to touch or thread the film.

Even today, its grainy and lo-fi aesthetic is emulated through filters found most popularly on social media applications.

35MM

After the flexible film was invented, Thomas Edison focussed his energy on developing the kinetoscope and the kinetophone. Ever since March 1892, Eastman and New York's Blair Camera Co. supplied Edison with film stock for a period of three years. A simple adjustment for sound information to the 40mm film gave rise to the 35mm which Edison tried to patent later.

This was one of the most popular formats of the analog age. It was perforated on the sides so that the projector and camera can pull the film accordingly. Standard perforation rates are about 4 perforations per frame, which would lead to about 16 frames per foot of film. This has been by far the longest surviv-
