

KEY

 Less than one millionth of a second after the detonation, a fireball of a radius of 0.63 km forms. A detonation above the surface increases casualties. The mass of luminous air and gasses expands rapidly, and rises into the air like a hot air balloon.

 The heat from the fireball causes a high pressure wave of compressed air that spreads outwards. Air blast with a pressure of 5 psi collapses most buildings, fatalities and injuries are widespread. A detonation at the height of 2.2 km achieves the optimum blast.

 A short lived ultraviolet pulse is followed by a destructive pulse of thermal radiation. Up to a distance of 7.6 km from the blast site, there is a 100% chance of severe 3rd degree burns – which are painless as the heat burns away the nerves.

 Air blast of 13.9 km radius, with 1 psi pressure. There are high intensity winds following the ball of compressed air expanding outwards. The glass windows of all the buildings shatter. The buildings undergo light damage.

HYDERABAD

Population: 68.1 lakhs
Fatalities: 14,09,300
Injuries: 22,99,830

**AHMEDABAD**

Population: 55.7 lakhs
Fatalities: 12,30,100
Injuries: 22,06,660

**KOLKATA**

Population: 45 lakhs
Fatalities: 20,99,520
Injuries: 36,64,380

**SURAT**

Population: 44.6 lakhs
Fatalities: 6,71,550
Injuries: 12,22,480
