

FOREIGN SATELLITES LAUNCHED BY INDIA

Earth Observation

Earth Observation satellites

are used for various remote sensing applications including meteorology, tracking land use, map making and monitoring the environment.

AIS

Automatic Identification

System are used for tracking and monitoring vessels in the sea, to identify and locate them as well as ensuring that they do not collide into each other.

Technology Demonstration

These satellites test out various kinds of new space technologies, and can include new materials, propulsion systems, or de-orbiting technologies.

Academic

Academic satellites are

built by students so that institutions can provide them first hand experience of working with various space technologies.

Communication

There can be various

kinds of communication satellites, but most such satellites launched by ISRO are geared towards providing various services to HAM radio operators.

Astronomical

Astronomical satellites are

instruments that use various payloads, including visible light, XRay and gamma ray sensors, and are often designed to observe a particular type of target.

Research

Research satellites have

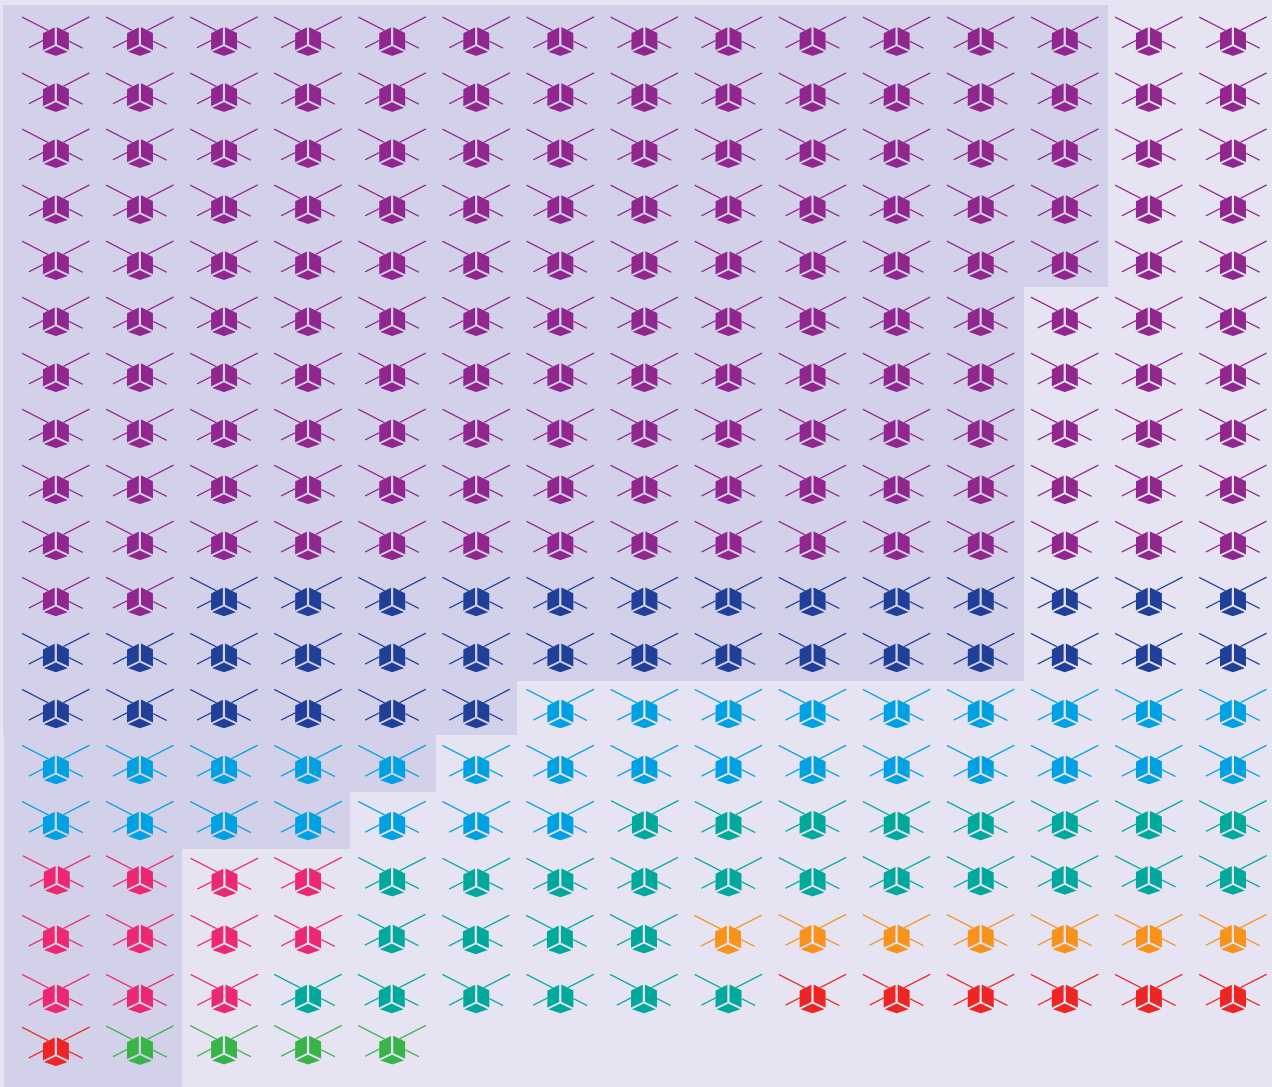

experimental payloads on board that conduct studies in the low gravity environment, once deployed in orbit, and then transmit the results back home.

IoT

IoT satellites are a subset

of communications satellites meant for use with IoT devices around the world. All four IoT satellites launched by India were deployed in the PSLV-C43 mission.

USA is ISRO's Largest customer

With 172 satellite launches, USA is by far India's biggest customer. USA does not currently have the capacity to meet the demand, which is going to change with the Space Launch System. The contracts are channelled through international intermediaries as regulations prevent US companies from using cheap Indian spaceflight.
