

change the resolution, as well as the DPI. It makes sense to use the same ratio as the original screen. The app automatically kicks in once you start up the target app that you want to use it with. A prompt will show up that you will get a confirmation message in case anything goes wrong. The first time you try a new resolution, it makes sense to allow this confirmation message. After you know the app has been working as intended, you can skip this confirmation message. Now, once you close the app, the resolution will revert to the original settings. The app does not permanently change the resolution and DPI settings of the entire OS. All apps may not work as intended, so instead of directly going for half the resolution and DPI, it makes sense to progressively reduce the resolution, till the target app that you are using begins to crash. This progressive tuning will give you the best possible performance. You can also add some low resolution buttons persistently at the bottom of the screen, to have access to critical system functions even when the resolution has been changed. These are provided through a bucket of simulated physical buttons.
