

increasing the frequency, the phone is going to run hotter and drain more power, but with better performance.

29 Pick a different CPU governor

The CPU governor is a profile that controls the increase and decrease of the CPU's clock frequency.

cy. Whenever there's a demand, the module will change the frequency as required based on the specific parameters set in it. These parameters are called tunables and every governor has a different one.

Basic governors that you'll find in kernels include Conservative, Interactive, Powersave, Performance and Userspace. If you want to know what these governors do, then you can check out a detailed description here: <https://digit.in/CPUGvrnrs>.

To change the CPU governor in your phone, you'll need a kernel companion app that either comes with the custom kernel or can be downloaded from the Play Store like Kernel Adiutor. Head over to CPU and tap on 'CPU Governor' under big governors and select the desired one. For the best balance in performance, it's best to keep it at Interactive. However, if you want the highest clock speed and don't care about heating issues, go for Performance. It all depends on your preferences since there can't be one best governor.

30 Increase headphone and microphone gain

Do you feel that your phone's volume sounds too low with headphones or earphones on? By default, Android doesn't allow you to increase beyond the system volume settings. However, with a rooted phone and access to the kernel, anything is possible. Open up Kernel Adiutor and head over to **Kernel > Sound**. Here, you can scale the volume beyond what Android allows by increasing Headphone Gain. Do note, this doesn't affect the volume of the loud speakers but only connected audio devices like headphones and earphones. The app also allows you to increase your microphone's input volume from Microphone Gain.

the top, enable 'Apply on boot' and reboot your phone. With that enabled, you'll have to enable an experimental feature Google Chrome using the flags. So, naturally this is going to work better in the Chrome app but it should display an improvement in browsing speed on other browsers as well. Type "**chrome://flags**" in the address bar and search for 'TCP Fast Open'. Enable the feature and relaunch Chrome from the prompt.

32 Use Linux on your Android phone

Wait, isn't Android already Linux? Yes and no. While Android does use the Linux kernel, it does not offer the same desktop environment as Linux. However, it has ideal hardware

31 Improve internet browsing speed

While browsing the internet on Chrome, you might have felt that the pages load quite slow even if you're using a high-speed internet connection. If you want better speeds, then you have to tinker with how your phone handles TCP Congestion while connecting to websites. You'll need a rooted phone and a kernel companion app that allows you to change the techniques or algorithms used. We used our trusted Kernel Adiutor app for this. Inside the app, open the left menu and go to Misc under Kernel. Here you will find the TCP Congestion Algorithm option. Tap on it and select 'cubic' out of the other algorithms. On

capabilities to run the same which is why we're going to show you how you can run Linux on your Android device. There are two ways you can do this - one that doesn't require you to root your Android device, while another does. The first method requires you to install
