

Debian noroot, a no hassle app that unfortunately hasn't been updated since 2015. It may not work well with Android versions post Lollipop, if it works at all. However, it does bring Debian Jessie on your phone with a compatibility layer. This allows you to run Debian apps without rooting. It might be a bit difficult to work with this app, which is why we recommend the rooting method.

On a rooted device, you can use the Linux Deploy tool to install various versions of Linux. First, you need to install Busybox from <https://dgit.in/BsyBx> and then install Linux Deploy from <https://dgit.in/LinuxDploy>. When you run it for the first time, tap Start to ensure the root permissions are enabled, then tap the Settings button in the bottom-right corner. Use this options menu to select your preferred Distribution. Debian, Ubuntu, Gentoo, Fedora, and many more are available to install. You'll need to hit the Enable box under GUI to view a Linux desktop on your phone, and ensure that VNC is selected for the Graphics subsystem. Next, check the screen resolution under GUI settings, and make sure that you're happy with the Desktop environment. Finally, find the User name and User password entries, and either make a note of them, or change them to what you prefer and can remember. Hit back, and then tap the three dots in the upper-right corner and select Install, then OK. When this is done, install VNC Viewer from the Play Store. In Linux Deploy, tap Start to run Linux. Then open VNC Viewer, and connect to localhost:5900 to view your Linux desktop with the credentials you entered earlier. Once up and running, you can install Linux software using the terminal in the usual way.

33 Pick the best I/O scheduler for you

I/O schedulers handle all the I/O operations between the system and the storage. Essentially, it tries to prioritise certain process requests and ensure that all the running processes are given enough storage bandwidth for a seamless experience. Just like CPU governors, there isn't one single best scheduler out there. You'll have to pick the best according to your needs among the many. For a detailed understanding of what every scheduler does, head over

to <https://dgit.in/IOSchdl>. Your kernel or phone might not list down all the schedulers, so you'll have to pick one from the available ones. How do you change the scheduler? Well, we take the help of our trusty friend Kernel Adiutor. In its left side menu under Kernel, tap on I/O Scheduler then the first option Scheduler. Tap on the scheduler that you've decided, enable 'Apply on boot' and then reboot your system.

34 Install a custom ROM for more features

Whatever Android phone you're using, the manufacturer always limits a few features, locking away a lot of potential. This is where custom ROMs come handy since they take things to the next level where some of them even provide regular update cycles. LineageOS is one of those and the community handling it is extremely active in sending out updates. They also have incredible support for almost every Android device out there. It can be downloaded and flashed using a custom recovery just like any other custom ROM. Head over to their downloads page (<https://dgit.in/LOSdwnld>) and search for your device. Take a backup before you flash the device. When inside the custom recovery, format data and then wipe system and cache. Copy the file to your internal storage and flash the file. Don't forget to install gapps before booting into the system. Optionally,

you can also install the LineageOS SU add-on if you want to root your device. After installation, reboot the device.

35 Install Google Camera ported app

Although the Pixels take impressive shots, many features added in the Google Camera app is responsible for those as well. However, the same app isn't readily available for every device out there. Numerous developers on XDA worked hard to port the camera app from the Pixel devices to make it compatible with a long list of Android devices. If you wish to enhance your photographs then head over to the Google Camera Port Hub on XDA (<https://dgit.in/GCPH>). Look for your device that will take you to its respective XDA thread. Download the APK and install it on your phone. Some devices might require you to flash an additional module as well.

36 Change the theme of your system

Apart from installing icon packs, applying different wallpapers and changing the accent colour, there isn't much you can do to change the look of your Android system. If you want to give your system a complete overhaul then you will require a theme engine. Earlier, changing the theme always required root access but that has changed now. Enter Substratum, a theme engine that will enable you to change different aspects of the system from a single location. Although Google stopped allowing this in Android Pie, users running Oreo and below still take an advantage of it. Substratum does work without root but not all the aspects will be editable. If you want system-wide changes to the theme, then you will require root access. It can be downloaded straight from the Play Store and within the app, you will find a tab where it lists all the supported themes.
