

Bugatti Baby II

'C

heap' and 'Bugatti' aren't terms you expect to hear in the same sentence, but the Bugatti Baby II is here to change that... somewhat. Based on the original racing car Bugatti Baby, the Baby II has been modernised for 2019. With a price tag of 30000 euros or roughly ₹24 lakhs, it comes with dedicated modes for kids and adults as well. In terms of proportions, the Baby II will be one third the size of the original Baby and will feature a 3D printed frame. The rear-wheel-drive electric powertrain comes with removable lithium-ion battery packs, and the car features a limited slip differential and regenerative braking. The 1.34bhp child mode

tops out at 20kmph whereas the 5.36bhp adult mode can reach 45kmph. However, if you'd like even more speed you can opt for the additional upgrade Speed Key which removes any speed caps whatsoever and pushes the vehicle to its limits with 10kW of power, delivering a total of 13.4bhp. The Bugatti Baby features the traditional French Racing Blue finish with other options available as well. It gets leather seats, a signature Bugatti turned aluminium dashboard, custom Bugatti instruments, and a scale recreation of Type 35's four-spoke steering wheel. The wheels will feature an eight-spoke aluminium design. Only 500 Bugatti Baby II units will ever be made.

Daher TBM 940

S

ucceeding the flagship TBM 930, the Daher TBM 940 turboprop brings a host of features that include an autothrottle, increased automation for the de-icing system and a redesigned interior. The most important feature among these is the autothrottle. Among standard production turboprops of this size, The TBM 940 is the first to pack this system. Based on a preset flight profile, this feature allows the engine to automatically adjust the aircraft's speed as it climbs following takeoff and as it gets ready to land. Not only does this bring down the pilot workload, but it also makes the takeoff and landing more efficient. According to Daher, the TBM 940 can reach a max cruising speed of 380mph. In optimal conditions, that speed grants the aircraft a range of 1660 miles. However, in the long-range mode at a cruising speed of 290mph, the aircraft can squeeze out 1,990 miles with only 37 gallons of fuel burning per hour. In addition to autothrottle, the Daher 940 comes with a deicing system. This system alerts the pilot when it detects ice and also clears the airframe, windshield, propeller, and the engine's particle separator. In the passenger section of the cabin, which seats four people (a fifth passenger can sit in the cockpit next to the pilot), Daher redesigned the seats so they are more comfortable, and it added more thermal insulation to the cabin sidewalls, along with a central shelf with side storage, an extra 115V electric outlet at the right rear seat panel, and a USB port bringing the total to six passenger and three pilot ports.

Goodyear Aero

A

s automotive and tech companies alike look towards a future with flying cars, tyre manufacturers have an interesting task ahead of them - to keep themselves relevant when roads are no longer needed. Goodyear has taken a step in that direction with the Aero, a two-in-one tyre design for the autonomous flying cars of the future. The Aero tyre doubles up as a propeller for flying cars in an interesting way. It uses a bimodal system which allows the tyre to act as a normal tyre on the road, without the need for air to be filled in. Keep in mind that the design is particularly narrow, and not

suitable for certain vehicles. In the 'flying mode' the tyres tilt 90 degrees and spin parallel to the ground. The spokes in the design that support the tire structure on the ground are also designed to act as propellers, which brings the airborne capabilities like providing lift. According to Goodyear, the system would use magnetic propulsion that would reduce friction as well. Using a combination of optical sensors and artificial intelligence, the tyre system also claims features such as analysing road conditions, wear and tear and more to provide suggestions regarding which mode to use during the driving/flying experience. Some of these concepts, such as the non-pneumatic structure and intelligent tire capabilities are already in development today.
