FIGHTING THE INSULIN BATTLE

Oral delivery of insulin could be the best weapon against this global epidemic.

Arnab Mukherjee | arnab@digit.in

Just looking at the numbers is enough to understand that diabetes is a global epidemic. According to the WHO, the global prevalence of diabetes among adults over 18 years of age has risen from 4.7% in 1980 to 8.5% in 2014. They have also predicted that India might have about 98 million people with Type-2 diabetes by 2030

– that is equivalent to the current (estimated) population of the United Kingdom, Australia and Denmark combined! One of the major factors in controlling the risks of diabetes is the easy availability of insulin, however, according to research from Stanford, insulin will be beyond the reach of around half of the adults suffering from type-2 diabetes by 2030.

For people with advanced type-2 diabetes, the pancreas is unable to produce enough insulin, and it has to be injected regularly to manage blood

sugar levels. However, according to research, the treatment complexity involved with using a syringe and a vial is often a strong deterrent from sticking to a proper medication schedule. While insulin pens have shown improvement over syringes, science might be on the verge of making things even simpler, with a pill.

THE CHALLENGE

Oral delivery has proven to be a preferred method of administering medication due to its non-invasive
