

Don't buy a console now

The next generation PS and Xbox consoles are just around the corner.

Google to check for bad experiences or peculiar behaviours associated with a power supply before you decide to take the plunge.

You will also come across Digital power supplies. These are simply power supplies which make use of a digital circuit for the feedback mechanism and to alter the power output. Since

there's a microcontroller involved, digital power supplies also come with USB connectors that allow you to read the feedback and sensor data from the power supply. So you can use a PC monitoring software to know exactly how much power the PSU is consuming or has consumed over a certain period of time. They're not necessarily

better but if going digital allows the PSU to react faster to changes in the power characteristics, then Digital is the way to go. This isn't a hard and fast rule, a crappy ODM could mess up a good PSU by bringing about unnecessary changes. If you can keep all of this in mind, then your next PSU might just last you a few years. **4**

BUYING ADVICE

A VFM PC

Q Hey Agent001, I am looking forward to building my first PC this year. I want it to have the best value for money and therefore, top specs available in my low-to-mid budget. As AMD processors have currently the best value for money, I will put an AMD. But should I wait for Zen 2? Is it worth the wait? Also in the last Digit Ultimate Buying Guide, you forgot to put down what to consider while buying RAM. Thanks in advance.

—Adityan Singla

Avoid large heat spreaders

A Hey Adityan, With memory modules, you need to ensure:

1. That they're of the same batch since manufacturers do switch NAND chips between manufacturing cycles and this comes into play when you run tight timings on your memory during overclocking.
2. That the heat spreader is properly affixed and is not using cheap sticker tapes for plain aesthetics
3. That the heat spreader height and width does not extend too much. This

may cause difficulties while trying to install a graphics card in the PCIe slot right next to the RAM slots or while mounting aftermarket heatsinks which have a low clearance.

4. Avoid cheap RGB since too much current draw by the LEDs gives less current for the NAND chips to work with. Subsequently, this affects your overclocking potential.

Coming to your question about waiting for Zen 2. Yes, you most certainly should wait for Zen 2. Going by the announcement made by AMD at COMPUTEX 2019, it seems that AMD might have single-threaded and multithreaded advantage in the desktop CPU segment. So there will be sizeable performance increments across all usage scenarios. Benchmarks should be out in the open by July 7, 2019 so you'll get a better idea by then.

A NEW GAMING LAPTOP

Q Hi TeamDigit, I am planning to buy a new gaming laptop in few months. Intel's 9th gen CPU has been released for notebooks in April, 2019 and still very few laptops are available to buy which contains 9th gen processor and only MSI released those laptops.

For the past gen laptops, I am getting the main specs as following: i7 8750H and gtx 1060 in under 100,000k or 1 lakh rupees. If I consider new gen processor laptops, I am getting i7 9750H and gtx 1650 in approx 1 lakh rupees and gtx 1650 has very less performance as compared to gtx 1060. And the one with gtx 1660Ti is very costly above 130,000k rupees. So, should I wait more for new

laptops or consider buying gtx 1060 laptops with previous gen processors (which I am avoiding because they are outdated and more than a year old). I will be buying in next few months. Please suggest a good laptop in my budget (1 lakh).

Thank you,

—Rahul Bagga

The GTX 1060 is still a good GPU

A Well, the 1660 Ti (Laptop) is slightly behind the 2060 (Laptop), so it will be quite expensive no matter the processor. As for picking between an Intel Core i7-9750H vs an Intel Core i7-8750H, you aren't getting that much of a performance difference since the 400 MHz frequency bump will only come into play in very few situations, especially considering that both are gated to 45W TDP. With the upcoming AMD refresh on laptops, you should expect NVIDIA to counter in some form or the other. This might lead to price drops or the introduction of new SKUs to offer a more competitive solution. If Navi does come to the mobile form factor, then you should see even more price drops. So I'd say you should wait a month and see how things pan out. If not, then the 8th Gen 8750 or 9th Gen 9750H + GTX 1060 combination is the way to go. **4**
