

Sexist Assistants

Research reveals that voice assistants are worse at understanding commands by women. <https://dgit.in/june19-36>

Rating system change

The Play Store rating system now gives more weightage to recent reviews. <https://dgit.in/june19-37>

ships in a text. This is particularly useful for extracting key phrases, places, people, brands, or events; identifying the language of the text and in understanding how positive or negative the text is. By classifying text, it automatically provides a collection of text files according to topics.

5. Azure Language Understanding Intelligent Service (LUIS):

It is described as, "a service that enables user to quickly deploy an HTTP endpoint that will take the sentences being sent and interpret them in terms of the intention they convey and the key entities that are present, it has a web interface that can custom design a set of intentions and entities that are relevant to an application and guide user through the process of building a language understanding system."

6. Azure Bing Spell Check API:

It uses natural language processing to help users in correcting spelling errors, recognizing the difference between names, brand names, and slang, and in understanding the various homophones in their text.

7. Azure Web Language Model API:

This is a REST-based cloud service API which provides various tools for natural language processing. With the help of this API, users can deploy the power of big data through language models trained on web-scale corpora collected by Bing in the EN-US market in their applications.

8. Azure Text Analytics API:

This API features a collection of text analytics services which provide APIs for keyphrase extraction, sentiment analysis and topic detection for English and 120 other languages text.

9. Azure Linguistic Analysis API:

This API uses the power of natural language processing (NLP) to identify the structure of a text and do analysis. It gives three types of analysis that are sentence separation and tokenization, Constituency parsing and Part-of-speech tagging.

10. Azure Translator Text API:

This is a cloud-based machine translation service. It supports machine translations in multiple languages that account for more than 95% of the world's gross domestic product. This API can be used to develop websites, applications, tools, or any software solution that requires multilanguage support.

11. Google Cloud Translation API:

It features an easy to use, simple, programmatic interface for translating an arbitrary string into any language using advanced Neural Machine Translation. This API is extremely responsive, and hence, applications and websites can integrate with it for dynamic, translating the text from the source language to a target language. For instance, from French to English. The distinguishing factor about this API is that it uses TensorFlow Recurrent neural networks for translation. Therefore it gives very competitive BLEU scores for selected languages – mostly European - Machine Translation. This API can be used to provide website translation for dynamic content or sequentially via API to provide intermediate translation for pending translation items.

12. Google Cloud Natural Language API:

This API offers machine learning models in an easy to use REST API and helps in revealing the structure and intention of the text. It can also be used to extract information about places, people, events and many more things that are mentioned in news articles, text documents or blog post. This helps in understanding the sentiment about various products on social media. It can also be used for parsing intent from the customer conversations that happen in a call centre or app.

SPEECH RECOGNITION

These software models are designed to allow applications to comprehend and understand spoken language and ac-
