

Nike uses AR tape

Nike has begun utilising AR to correctly identify the size of your feet and find shoes for you. <https://dgit.in/june19-38>

Incognito everywhere

Google has announced that Maps and Search would be getting an Incognito mode. <https://dgit.in/june19-39>

cordingly convert these conversations to text. Here, NLU (Natural Language Understanding) along with speech recognition and intent analysis, provides us with knowledge about what the user wants. The most familiar example of this technology in action is with Apple's Siri, Google's Home and Amazon's Alexa.

There are a variety of MLaaS speech recognition tools like Amazon Transcribe, Azure Bing Speech API, Azure Custom Speech Service, Google Cloud Speech API and Google Dialogflow Enterprise Edition.

1. **Amazon Transcribe:** It is an automatic speech recognition (ASR) service making it easier for adding speech to text capability in various types of applications. Amazon Transcribe API enables you to analyze the audio files that are stored in Amazon S3 make it return a text file of the transcribed audio speech.
2. **Azure Bing Speech API:** It is a cloud-based API providing advanced machine learning algorithms to process spoken language. Because of its responsiveness, it can be used to add speech-driven actions even in applications that include real-time interaction with the user.
3. **Azure Custom Speech Service:** It is a cloud-based service providing customized speech models for

Speech-to-Text transcription.

4. **Google Cloud Speech API:** This API enables the conversion of audio files to text by using neural network models in an easy to use API. It recognizes more than 80 languages and variants spoken across the globe and can even transcribe the text of users who are dictating to an app's microphone. It also provides command-and-control through voice and transcribing audio files besides many other applications.
5. **Google Dialogflow Enterprise Edition:** It is an end-to-end development platform used to build conversational interfaces for mobile applications, websites, messaging platforms, and IoT devices. It can recognize the intent and context of what is spoken as it is powered by machine learning. Hence, it provides highly accurate and efficient responses.

COMPUTER VISION

Computer vision is an advanced deep learning technology that helps applications in recognizing and understanding images and videos. Using the computer vision convolutional neural network algorithm, one can identify and classify multiple specific objects and people, and tag them. The following MLaaS offering provides computer vision:

1. **Amazon Rekognition:** It is used for adding image and video analysis to software applications. It is used to identify the people, objects, scenes, text, and activities, and inappropriate content from images or videos.
2. **Azure Computer Vision API:** This is a cloud-based Computer Vision API. It provides access to advanced deep learning computer vision algorithms for processing images and returning information. It analyses visual content in a variety of ways based on the inputs and user choices on the uploaded image or specified URL.
3. **Azure Content Moderator:** The main aim of this service is to flag, assess, track and filter out offensive and unwanted content, which creates risk for a particular organization. The content to be moderated may be text, images, or videos.
4. **Azure Custom Vision Service:** It is a tool to develop custom image classifiers. Vision Service makes it easy and quick to deploy, build, and improve an existing image classifier. It also provides a REST API and web portal to upload the images and content for classifying.
5. **Azure Face API:** It is a cloud-based service providing advanced face algorithms. It detects the face with attributes and also recognizes the face.
