writing) and the ambient temperature within the chassis. This ambient temperature is usually around 35-40 degrees celsius for most folks with an air cooling setup. 3D NAND is rated to have the highest endurance rating, if the temperature is 40 degrees celsius. The controller, on the other hand, prefers the temperature to be as low as possible. Since the chassis ambient temperature and the SSD temperature are going to be different,

it makes sense to have a proper heat sink attached to the SSD. One that is preferably attached to the controller and not the NAND since reducing NAND temperature isn't advised at these values. However, enterprise SSDs tend to use NAND that are rated to run at much higher temperatures. That's an additional consideration when deciding to get a heatsink for your SSD. Ideally, you should avoid an air gap between the heatsink and

the SSD like what some motherboards have and is known as an "SSD shield". This simply isolates the SSD from the graphics card but causes the temperature to rise. So if you're planning on installing an SSD, you need to verify if the temperature of the controller and the NAND are within spec. If the temperature is too low or too high, then you will reduce the life of your device. While it may be easy to install an SSD, it's not necessarily the right choice. 

BUYING ADVICE

WIRELESS WALKMAN

Q Hello, lately I have been on a hunt for wireless earphones that support Bluetooth and is also a standalone MP3 player. My research led me to the Sony NW-WS623. It has all the features I've mentioned above but the price is a whopping Rs. 8000. Also, I have heard some negative feedback that its sound quality isn't all that great. Now I have come to you, to help me make the right purchase. I don't want to waste a huge amount of money on a mediocre product.

Kindly provide your views on Sony NW-WS623 and suggest any alternative if you have.

—Abhishek Solanki

Sony NW-WS413

Hi Abhishek,

The sports MP3 player/wireless walkman category have very few models available from for anyone to choose

from. Aside from the Sony NW-WS623 you can get a few more models from Sony, such as the NW-WS413 and the other notable model from another brand is the JBL Endurance Dive which is aimed at folks who want to listen to music while swimming. These units are expensive because of the lack of competition which is why you feel it's unfair to pay such a high amount for these units. You might find a few cheaper alternatives on Ali-Express but I'd say you can opt for the WS413 since it is cheaper and the audio quality doesn't differ much. Even from the perspective of the feature set, you are only losing out on a few quality-of-life features that most folks can easily do without.

MICROSTUTTER NUISANCE

Q Hi,

I'm using an AMD Ryzen 5 2600 paired with a Vega 56, 16 GB of DDR4 RAM, a WD Blue SSD and the rest are from an older machine. The PSU is a Seasonic Focus Gold 650W. The build process went well but after installing Windows 10, I notice a bit of stuttering on Windows. So I re-downloaded all the drivers fresh from the respective web sites.

After doing all this, the problem still persists in everything, normal day-to-day tasks and gaming. Sometimes, the games stutter at really low FPS which is quite irritating. I've run benchmarks and reset everything to default settings and I don't know what else to do. Thanks!

—RGB-Walla

Hey RGB-Walla!

I noticed something similar with the first gen Ryzen but after a few AGESA updates, that sorted itself out. My usual course of action was to set the RAM to 2666 MHz which is the default for 1st Gen Ryzen and 2933 MHz for the 2nd Gen Ryzen. So I'd start with that and then push my luck at bumping the RAM to 3200 MHz.

AMD Ryzen 5 2600

The other thing was to set the RAM timings manually in the BIOS. This was essential for some benchmarks such as Cinebench to get better numbers. Ryzen CPUs love higher RAM speeds but if the timings go for a toss, then you will experience these micro-stutters.

Also, you should install LatencyMon and see which driver has the highest DPC count. I'd switch out that as well since anything with a high DPC count is literally nagging the processor for some "me-time". Another thing you can check is if Record Desktop is turned on in AMD Radeon ReLive. That's known to cause microstutters.
