

Google launches Gallery Go

Gallery Go is lighter and less data-hungry at just 10MB, a fraction of the 130MB size of Google Photos. <https://dgit.in/aug19-29>

Free Joy-Con repairs

Not only will Nintendo not charge for the repair, they'll allegedly offer refunds for those who did pay. <https://dgit.in/aug19-30>

accents and more, it would make sense to have an AI assistant that was more in line with those nuances. That's where a voice UX designer steps in.

Google Translate may have caused many to believe that their degree in Linguistics is now rendered useless, however, it's really not. Companies are being rather aggressive with integrating voice as a platform which enhances digital-customer engagement strategies. Studies indicate that the more a person is able to connect with a voice interface which reflects their dialect and unique speech traits, the more effective the communication between them is. It's not rocket science really, we connect more with what is familiar. However, developing such targeted solutions may be close to rocket science. Hence, voice UX designers have an extremely difficult but rewarding job of making the voice UX more approachable by everyone. This can amplify customer engagement, lower customer acquisition costs, improve task completion, and optimise how effectively the voice assistant handles our requests.

MAN-MACHINE TEAMING MANAGER

Machines cannot, in their present state, take over the art form in jobs (emotion/empathy, contextual judgement, experience, ethics and more).

The man-machine dream team

Machines are pacing (or galloping, in some cases) ahead of humans in the science of jobs (computational abilities, data analysis, pattern recognition, action determination and more).

However, one doesn't have to triumph over the other. When you combine the strengths of humans and machines together, you may have just created the dream work team. Human-machine collaboration may very well be the new hybrid workforce in the next decade. To ensure transparent communication between the two, translate consumer and employee needs and well as make them understand business strategies, a new role of a

man-machine teaming manager is emerging.

This work profile requires candidates to develop an interactions system for humans and machines to communicate with each other their capabilities, goals and intentions. They also need to devise a task-planning system for the collaboration

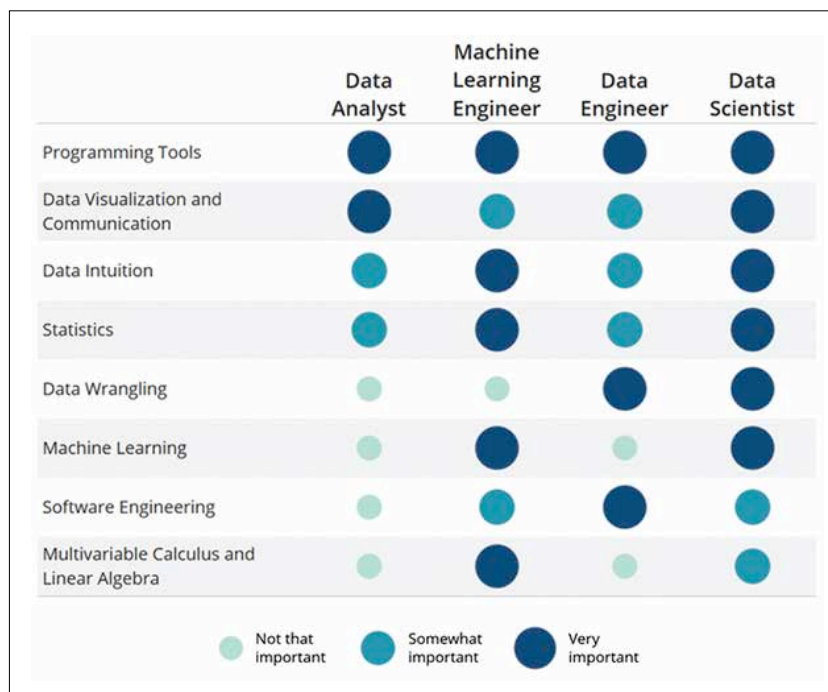

between humans and machines. Both forces need to become collaborative colleagues to achieve great efficiency. A man-machine teaming manager must identify tasks, processes, and ex-

periences that can be upgraded using new technologies.

MACHINE LEARNING ENGINEER

This is a job profile that already exists and for quite some time actually. However, this is probably one of the few that is not going anywhere for the foreseeable future and this job will actually rise up in prominence over the years, even more than what it is now. Simply because ML and AI will enter almost every domain, product, career, and household in the next decade. A 2019 report from Gartner shows that enterprise applications for AI and ML have increased by over 270 per cent in the last four years, and there is an ever-rising demand for ML engineers.

Machine learning engineers are basically advanced-level programmers that develop AI machines and systems. They know everything there is to know about programming, work with complex datasets and algorithms to train these ML systems to their best potential. Companies hiring ML engineers are not only companies like Google, Amazon and Apple but also an array of startup AI companies that specialise in niches.

Important criteria/qualifications for an ML engineer, and a couple of other tech jobs
