

999999999 in one

Surprisingly enough, those old 8 bit cartridges are still available, and you can even pick them up in bulk. <https://dgit.in/sep19-53>

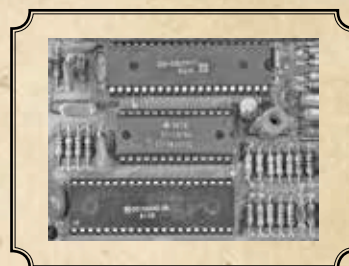

Sega Saturn

Have your fill of nostalgia with these old issues of Sega Saturn magazine. <https://dgit.in/sep19-54>.

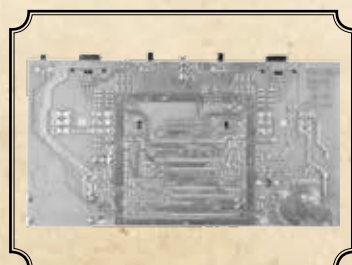

The (ancient) processors

Upon further inspection, the Atari 2600 was found to have a 1.19MHz 8-bit processor, 128 bytes (yes, bytes) of RAM, 192x160 resolution, 128 colours, with a maximum of four colours per line, and a dual channel mono sound. The Atari 2600 stores games in ROM chips that are housed in external cartridges, as mentioned above, which allows for potential playability of infinite number of games on the console, unlike other consoles in this era.

Custom chips and lack of external RAM

The chips featured in the image are the 6532 Ram-I/O-Timer (RIOT) chip and MOS Technology's 6507 CPU. These were manufactured by Synertek and Rockwell respectively. Atari's own custom chip, the Television Interface Adapter (TIA) allows for multiple colours, increased graphics and sound. The video processor has no external RAM, owing to the exorbitant price of memory at that time.

Flipping it around

The backside of this console's motherboard has really nothing interesting on it, except for indents for through-hole soldering and hand-drawn circuits. You can also see the company's name, revision 13 and 1980 written on the back. The console is extremely repairable and replacing, say a burnt out resistor or IC is very feasible.
