

better for darker images, and not as well for bright ones.

1. Next, add an overlight. These are light leaks where the film has been accidentally exposed after the image has been clicked. There are a number of light leaks options to choose from, and the transparency of each can be adjusted. Tap on the tick mark to add it to the image. You can also layer on multiple light leaks of varying transparencies on the same image, by tapping on the light leak option again.
2. Next, add a texture. These are grains or scratches on the image after it has been printed, or on the underlying film itself. Like the light leaks option, it is possible to layer on multiple textures, and adjust each of the transparencies individually.
3. Add the filters. This is a basic filter that allows you to provide a nostalgic look and feel for the image. This step can be skipped. You can also add glitch effects to your image, but this step can also be skipped.
4. Next is the date stamp, and you can provide a date and timestamp style to add on to the image. This is a premium feature.
5. Finally, there are a number of adjustment options on the app, including contrast, vibrance, saturation, temperature and sharpness.

On the top right corner is the export button that saves the image to the camera roll, and allows you to share the image on social media. And, you are done. While the base app is free to use, a subscription unlocks additional effects including glitches, filters, light leaks and textures. An alternative app with most of these options, and more expansive light leaks as well as dust/scratches for free is called 1998 Cam. This app is particularly good for light leaks as it allows you to change the orientation, hue and opacity of light leaks. For more granular control, the

FILM IN 8MM

8mm film was the original format for shooting home videos, released in the 1930s by Kodak. Now, you can get the experience of shooting in this jerky format using your smartphone. To do this, we will be using an app called 8mm Vintage Camera.

1. The interface of the application looks like a camera. You can either use the red button to record a video natively, or choose the gear icon to process a video that you have already shot.
2. It is a good idea to change the settings before you start to shoot natively. There are two aspect ratio options available, as well as quality option, which ranges from 480p, and supports up to 4K.
3. On the top right corner of the app is the lens option, which is one type of filter that can be added. There are "lenses" for super 8 and 16mm film, as well as colour fringing and light leak options. The other options are for frames and scratches.
4. Next, is the heart of the app, which is the number of film options. These can be set on the bottom left corner of the app. The option sets the look and feel of the video, and allows you to simulate cameras from a particular decade of your choice. The ones we particularly like are 1920, 60's and noir.
5. There are even retro options for recording the sound. You can simulate the sounds of a projector playing back, or just make a silent movie.

Note that the application does not let you take photographs at all, and restricts itself to shooting videos. This is a paid app that costs ₹249, but is well worth the investment. There are no microtransactions. When the makers of the documentary Searching for Sugar Man ran out of 8mm film, he used the app instead to complete the movie. The film went on to win an Oscar, so the application has proven to be pretty authentic.

best option is to understand the features of both the applications, and use them both on the same image.

CAPTURE THE FEEL OF FILM

One of the joys of taking photographs with film cameras, was in choosing the film. Every type of roll of film had a particular look and feel, as well as a speed. To do this, we will be using an app called RNI Films.

1. Fire up the app and select Load Photo. There is no option to use the camera directly in this app.
2. On the top right corner is the crop option. There are a range of vintage ratios available including 3:2 and 5:4.
3. Now select a film type. The options available are vintage, negative, slide, instant and BW, for the various kinds of films used in vintage and legacy equipment. These colour profiles are authentically derived from the film stock. Agfa, Kodak, Fuji, Rollei options are available. Some options simulate deteriorated film stock, or ageing of the photo.

4. Next, you will need to adjust the settings. Drag the bar on the bottom to the left to access more options. The pre and post options allow you to change the colour temperature and tint before or after the target film colour profile is applied.
5. The grain option allows you to add noise. There are sliders for strength and size. Then there is the dust option, which randomly generates dust and scratches. Tap on the dice to change the pattern. Once you find one you like, drag the slider to increase or decrease the transparency.

Now you can export the photo to the camera roll. Shown here is the Technicolor 2 stock. You can also share the image directly to Instagram or Facebook.
