

CAPTURE COOL NIGHT SHOTS

The NightCap Pro app is just about the best app for long exposure shots. There are dedicated modes for astro-photography, which stack multiple exposures to produce images of star trails and meteor showers. There is also a dedicated mode for capturing the International Space Station, which can also be used on other satellites. You can

erful photo editing app, but the most compelling feature is its ability to create multiple exposures. First, start with a photo from portrait mode. Images with the new High Key Mono processing work great with this app. Then, pull in an overlay. A landscape shot works best here, as a subject matter not orientation. Urban environments also work great. Now, you can move around

also use the application with a tripod for more conventional captures, such as night time timelapse videos. The quality of the videos goes all the way up to 4K. The light trails mode is great for capturing fire-crackers or moving traffic. The application offers granular controls for exposure, ISO, focus and white balance. Bear in mind though that there can be a lot of noise in the images if you do not know exactly what you are doing. The application can also be controlled via the Apple watch, which makes it convenient for stargazing sessions. Shown above is an image of the M13 Globular Cluster captured by @andrew_malwitz (on Instagram) using the NightCap Pro app on an iPhone, using a telescope.

SIMULATE MULTIPLE EXPOSURES

Englight Photofox is a pow-

the overlay and adjust it to create photos that look like the old school double exposure shots.

TAKE CONTROL OF FILTERS

Mextures is essentially another filter app, but unlike any other. This takes the filter experience to the next level. You can add layer after layer of filters. Now the rotation, opacity and other parameters of each individual layer can be further adjusted. There are

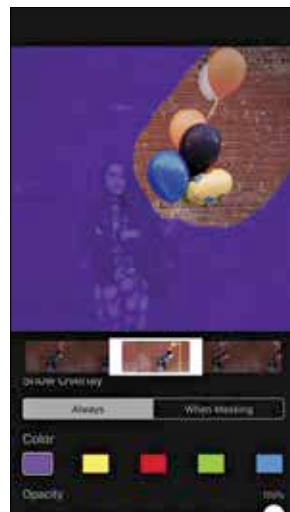

texture filter packs available, which are sorted by themes such as "Light Leaks", "Grunge" or "Grit & Grain". Also available are filmstrip filters that simulate the colour characteristics of particular film stocks. Each of these textures have twelve different blending modes. Once you have a perfect combination, you can save all the settings together in what is known as a "Formula". The Formula can be saved, and reused on other images. Also these Formulas can itself be shared with other Mextures users.

CAPTURE SUBTLE MOVEMENTS

The Cinemagraph Pro application lets you create a kind of hybrid between a movie and an image. While most of the image remains steady, a section of it has a movement that plays out in a loop. Think of a sunset by the beach where the waves are constantly in motion, a campfire scene where only the fire is moving, or a person holding a bunch of jumpy balloons. This is one of those apps that require a tripod to work properly. You can choose to import a video, or shoot one natively from the app. Once imported, you have the option of masking a particular area that you want to see the looping motion in. This area can be masked with your finger. Then, you have to trim the video clip so that the looping is perfect or

near perfect, with as little as a jump as possible when the loop starts over. The app does help you here, by giving you a bounce option to reverse the animation, and there is also a crossfade that you can control. Now, the actual movement observed may be too fast or too slow, so the app allows you to tweak the speed of the motion as well, for the most visually pleasing effect. There are plenty of options available for tweaking and editing the image. If necessary, you can add text overlays through the app itself. Now comes the exporting part, and this is where

the app really shines. You can export in H.264, HEVC, GIF or Live Photo. The app also allows you to directly upload to Facebook Ad Manager.

MIX AND MATCH

One of the best results are obtained by post processing an image through multiple applications. Try this one for example – capture a night time timelapse of moving traffic through NightCap, and then use the glitch effects from Hyperspektiv. Another combination you can try is capture a Hyperlapse, then use nception and finally process the video on Glitch Studio.
