

'show password' functionality most log-in forms have today, basically to double check whether you've input the right password.

Installing a bookmarklet is incredibly easy if you're using modern browsers. As simple as dragging and dropping the link to your bookmarks toolbar. For the purposes of this article, we'll show you the code itself that you need to save as a bookmark:

```
javascript:(function(){%7Bvar%20s,F,j,f,i;%20s%20=%20%22%22;%20F%20=%20document.forms;%20for(j=0;%20j<F.length;%20++j)%20%7B%20f%20=%20F%5Bj%5D;%20for(i=0;%20i<f.length;%20++i)%20%7B%20if%20(f%5Bi%5D.type.toLowerCase()%20==%20%22password%22)%20s%20+=%20f%5Bi%5D.value%20+%20%22n%22;%20%7D%20%7D%20if%20(s)%20alert(%22Passwords%20in%20forms%20on%20this%20page:nn%22%20+%20s);%20else%20alert(%22There%20are%20no%20passwords%20in%20forms%20on%20this%20page.%22);%7D})();
```

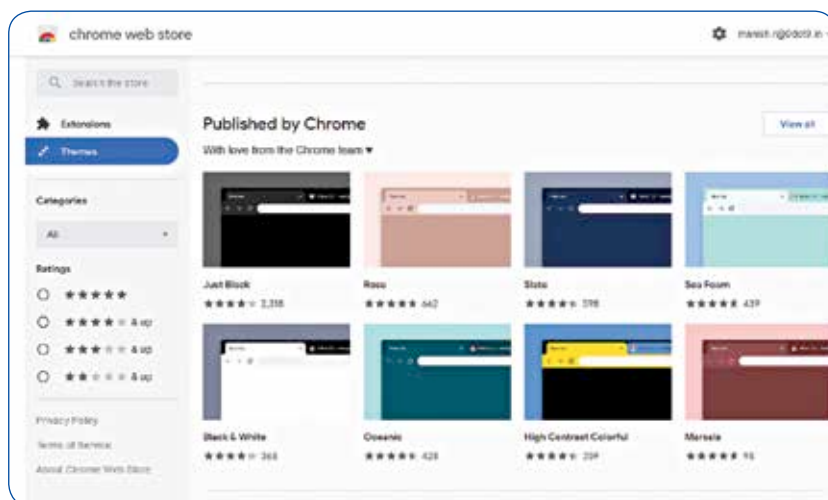

Simply paste that into your browsers address bar, and save that as a bookmark. Next time you're on a web page that has a password input, like Facebook or Gmail, try using this bookmark. It should show you whatever you have typed in the password form, between two "nn"s. So: **nnyourpasswordnn**.

Since bookmarklets need to be manually called upon, they're lighter on your system load than extensions.

You can find quite a few bookmarklets at <https://caiorss.github.io/bookmarklets> to get started.

USERSCRIPTS

Userscripts are like a combination of the two methods we've mentioned above, in that they're like bookmarklets (more JavaScript code) that always run when you visit the

Themes on Google Chrome's web store

specific website that they've been created for. However, in order to actually install and use userscripts, you usually need an extension. The most popular example in this case would be Greasemonkey.

Installing userscripts is incredibly easy once you've got the extension

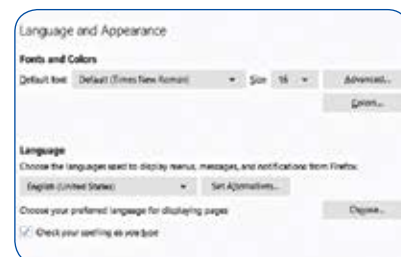

Some of the Userscripts on Openuserjs

downloaded. You simply visit your favourite Userscript archive and find the scripts you want, and install them. Your extension will automatically install them. The next time you open the website they pertain to, the userscript will automatically kick in. It's that easy.

The sites <https://openuserjs.org/> and <https://greasyfork.org/en/scripts> are currently your best bet for userscript

hunting. There are several useful userscripts, but you will have to find them in a large pile of Chinese specific ones, made to bypass all the ads and blocks they have in that country.

Using userscripts, you can alter the look of sites, or the mouse pointer, and pretty much get any look you desire,

Changing font, colour and Language on Firefox is easy via the Accessibility options

if you know how to code. If you can't code, just use the many userscripts that people have already created for the most popular sites.

THEMES

Much like extensions, themes are very obvious when it comes to customising your browser. However, unlike most of the stuff we've mentioned so far, they do nothing in terms of functionality, they primarily exist to turn your browser into eye candy. Regardless, they're popular because we love them everything!

Simply put, if you want your web browser to be able to do something that's not completely unreasonable, chances are, you can get your browser to do it for you. **A**

You can use bookmarklets to edit and alter web pages.
