

send a different, random one every day to a selected contact, at a random time (from a selected range).

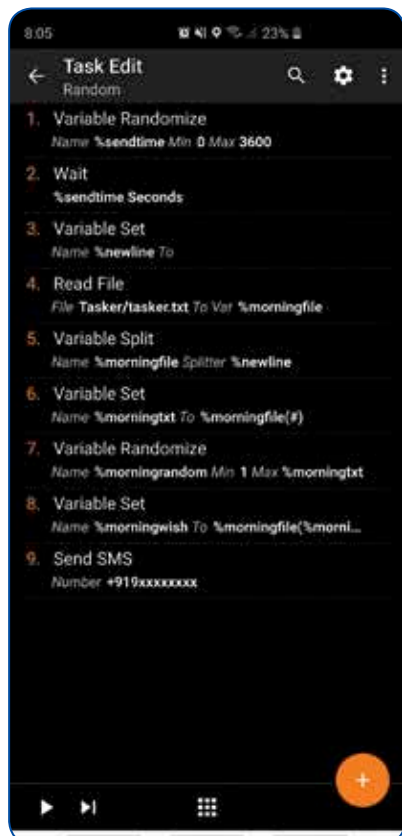

Firstly, create a .txt file with all your good morning messages, each on a new line. Save this file in your device's Tasker folder. Then, create a profile on Tasker with a name of your choice. Set the time to when you usually send your 'good morning' text out in the 'FROM' section. Say, 7:00 or 8:00 AM? Uncheck the 'TO' section and go back. Next, create a new task and name it 'Random Messages' or anything you fancy, really. Click the '+' icon on the bottom right and do the following:

Action 1: Variable Randomize [Name: %sendtime, Min: 0, Max: 3600]

Action 2: Wait [MS: 0, Seconds: %sendtime, Minutes: 0, Hours: 0, Days: 0]

Action 3: Variable Set [Name: %newline, To: Press 'Enter' button once, Do Maths: Off, Append: Off]

Action 4: Read File [File: Select your .txt file, To Var: %morningfile]

Actions to send random good morning messages with Tasker

Action 5: Variable Split [Name: %morningfile, Splitter: %newline, Delete Base: turn off]

Action 6: Variable Set [Name: %morningtxt, To: %morningfile(#), Do Maths: Off, Append: Off]

Action 7: Variable Randomize [Name: %morningrandom, Min: 1, Max: %morningtxt]

Action 8: Variable Set [Name: %morningwish, To: %morningfile(%morningrandom), Do Maths: Off, Append: Off]

Action 9: Send SMS [Number: Select from your contacts, Message: %morningwish, Store in Messaging App: off]

Now, you have created a Tasker profile to automatically send a random good morning message to the contact of your choosing from a list of messages you have listed out on the .txt file.

Note: The .txt file is only useful if you have tons of messages, say like 100 random messages (just to ensure your SO doesn't figure out they're automated). If you only have a few random messages, simply set several Variable Sets, add a name like %msg1, %msg2 and so on, and then add your random message in the 'To' field.

Additionally, you can also send WhatsApp messages like this daily but that is only available for users with a rooted device. If you do, simply install the WhatsTasker plugin and select send 'WhatsTasker Send Message' action as your message client. Also, you can enter your data in an excel sheet instead of a .txt file by using the Spreadsheet Tasker Plugin. Tasker is a paid app that costs ₹270.

DOWNLOAD GOOGLE CAMERA ON ANY ANDROID DEVICE

Pixel smartphones are often touted to be one of the best, if not the best, smartphone to click photographs on. The accurate portrait mode, Night Sight, relatively true-to-life colours and other software-enabled imaging abilities are a major pull for photo enthusiasts to buy the phone. However, if you do not own a Pixel device and still want to utilise Google Camera, many of you actually can! You will need to install the GCam Mod on your

Android smartphone, but before doing this, you need to check a few things.

Most importantly, your phone should have support for Camera2 API. This is a framework that lets developers get access to granular controls over the smartphone camera including exposure, ISO and more. The developers then integrate these granular camera controls into their own third-party

The Google Pixel smartphones' camera can be on your non-Pixel device!

apps. Unfortunately, not all phone developers have implemented this API into devices even today. Still, if you have a mid-range or flagship phone, chances are you have the API support. To check, you can download an app called Camera2 API Probe from the Play Store. After launching it, check the Hardware Support Level section. There are four options, and this is what each one means: 1) Legacy: No support for Camera2 API available; 2) Limited: Support for some, not all, Camera2 API abilities; 3) Full: Complete support available; and 4) Level_3: These devices have support for YUV reprocessing and RAW image capture. Our test device, the Samsung Galaxy S10 Plus has Full support for the rear camera and Limited support for the front shooter.

If your phone doesn't have Camera2 API support, then you can only enable it by rooting your device. You will need to edit the "build.prop" file on your smartphone or utilise Magisk to enable it. To enable it through the "build.prop" file, download the BuildProp Editor app and enter this line to the
