

Volume Keys app which lets unrooted devices perform this task. This is an open-source app which utilises the volume key long press listener API to change tracks even when the screen is off. To use this, you will need to have an Android device running Android 8.0 or higher.

Unrooted devices can finally use their volume keys as media controls

To set this up, firstly, install the APK for the app from Github (<https://digit.in/SkipTrack>) and run this ADB command:

```
adb shell pm grant com.cilenco.skiptrack android.permission.SET_VOLUME_KEY_LONG_PRESS_LISTENER
```

In order to run ADB commands, you need to first download the SDK Platform Tools on your Windows, Mac or Linux PC. Then extract the ZIP file to an easily accessible location. Next, on your Android device, go to Developer Options (unlocked by tapping Build Number 7 times quickly in Settings > About Phone). Enable Developer Options and then find USB debugging. Toggle the switch on.

Now, connect your phone to the PC with your USB cable. Set the USB mode to PTP, this can be changed in the notification shade. Open the platform-tools folder on your PC. Press Shift+Right Click and choose 'Open command prompt here'. Type 'adb devices' and hit Enter. You will now see a list of attached devices, choose yours and enter the ADB command mentioned above.

A COUPLE OF USEFUL XPOSED MODULES

If you have a rooted Android device, Xposed Modules are impeccable for customising and tweaking your Android smartphone. After rooting, you need to install an app called Xposed Installer. This allows you to download other apps which can modify your phone.

Note: After installing each of the following modules, remember to enable it. Navigate to the main menu in Xposed Installer and go to the Modules section. Here, check the box next to the Xposed Module you want to enable and then restart your phone.

YouTube AdAway

As the name suggests, this Xposed Module will remove all YouTube advertisements on the mobile app. It also works for YouTube TV, Gaming and Kids apps. This module can also disable video suggestion and information cards.

Snapprefs

This module allows users to auto-save Snapchat images and videos on Android. There are other features available as well such as paint, location spoofing, option to disable Discover and taking screenshots without alerting the sender and more.

GravityBox

This Xposed Module is used for modding and enhancing the features present on Android devices. You can tweak numerous things down to a granular level through this module on your lock screen, status bar, display, navigation keys and more.

BootManager

You can use BootManager to curb certain

apps from auto-launching every time the phone starts up. This can significantly improve boot time and battery life, especially if your phone has multiple intensive apps.

CrappaLinks

This module solves the aggravating problem of links opening up in a browser window within the app instead of going to the app itself. This is often observed with Google Play or YouTube links and the CrappaLinks Xposed Module fixes this issue.

XPrivacy

This Xposed Module can stop certain apps from accessing certain types of information. All you need to do is choose a category to block and then tap every app that should be restricted from accessing the corresponding information.

Deep Sleep Battery Saver

This may seem like just another Battery Saver on the surface, however, this is a powerful tool which can not only put your apps to sleep to conserve battery, but also force processor cores into a sleep state!

MinMinGuard

This Xposed Module is an ad blocker for applications only and does not block ads on websites. This ad blocker has an edge over other apps like this one since it doesn't just remove the ad content and leave the frame as an empty space like others do. It actually removes the entire space in the app where the ad used to reside.
