

Take a trip through the cosmos

Here's the NASA site which posts a new Astronomy Picture of the Day every single day. <https://digit.in/mar20-05>

WTF

Space-bar?

There's a gas cloud near the constellation Aquila that contains enough alcohol to fill 400 trillion trillion pints of beer. <https://digit.in/mar20-06>

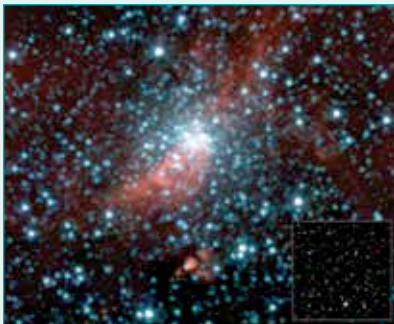

Astronomical instruments capture spectacular images of objects in the cosmos all the time, but these may not go viral or make the headlines. All of these images have advanced our understanding of the universe.

↑ This is M87, the galaxy containing the supermassive blackhole which was the first to have its shadow imaged. Shown here is a relativistic jet emanating from the black hole, the material stretches across a distance of almost 5,000 light years.

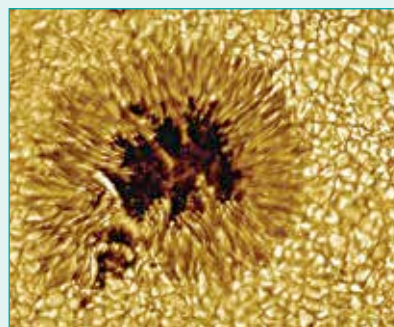

← This region of the sky appears empty to the naked eye, but in the infrared spectrum, the Spitzer Space Telescope found a globular cluster with 300,000 stars.

← This capture of NGC 602 star cluster shows that the energetic radiation from the young stars are pushing away the star forming material into new regions.

← Daphnis in the Keeler Gap creates kilometer-long ripples. Images such as this one allow scientists to understand the interaction between Saturn's rings and moons.

← This close up of a sunspot shows the magnetic field of the Sun preventing hot material from entering the cool spot. Each of the cells of hot gas surrounding the spot is called a granule.

← This image of the Orion Nebula was captured using a ground-based telescope at the La Silla Observatory in Chile. The red portions show glowing clouds of hydrogen.

← The mass from dark matter is responsible for this extreme example of gravitational lensing. Scientists informally refer to this galaxy group as the "Cheshire Cat".
