

We are all made of stars

The only known process that can create most of the elements that make up human bodies, as well as the world and the universe we live in, are the thermonuclear reactions that take place within the hearts of stars. The earliest stars were poor in metals and heavier elements, while the newer generation of stars burned the existing elements to create heavier elements through nuclear fusion. Everything you see around you, very probably originated in a supernova, or the big bang itself.
