GLAMOS

Designed by ex-Samsung engineers, the Glamos is a small device that's been designed to be able to turn any display into an interactable touch screen. It's also small enough to carry around in your pocket, so it's basically a portable virtual touchscreen for you to carry around.

When we say small, we mean small, at only 1.5 inches this will fit in just about anyone's pocket. It's also easy to use and requires no set up in most cases. It's as easy as plugging the device in and starting to use it as a touch screen. Of course,

it's still limited in the sense that the display you're using it with has to be a smart device's display. So as long as it's a phone, tablet, laptop, desktop monitor or smart TV, it should work with Glamos without any hitches.

Glamos works using LiDAR technology. It scans its surroundings and measures the distance between

itself and the display and then creates touch coordinates accordingly. You don't have to actually attach Glamos to the display, you can create a virtual touch display for it at a distance as well, up to 3 feet. Glamos also scales its virtual touchscreen's size in accordance with the display it detects.

Mojo Vision AR contact lens

Right now, most of us have experienced AR in some way or the other, be it through the super popular Pokémon Go or through some other app. For most of us, this experience has been through our mobile phones. Mojo Vision aims to add another way to experience AR, possibly, the most optimal way, directly through our eyes. That's right, we're dipping into the realms of science fiction here, AR contact lenses are a thing. The Mojo Lens AR lenses are "the world's densest" micro-displays, with 14K pixels-per-inch, wireless radio, image-recognition tech, and motion sensors. Imagine having access to all of that on your eyeballs. Being able to see directions while walking, being able to see steps to something you're building or cooking as you're doing it, without needing to refer to your phones or books, not needing to refer to a screen or notes during a presentation. The uses are endless. AR headsets are bulky and you definitely don't want to be wearing one of those out in public. Something as discreet as contact lenses is the ultimate solution. However, the lenses are still in the works, and there's the matter of privacy and security, Mojo Vision don't want the kind of trouble Google Glass had when it first launched.

Ubco FRX1

We've seen plenty of electric bikes in this section, but off-road electric bikes, not so much. That's exactly what the Ubco FRX1 is though, an off-road electric bike. There aren't that many companies globally that even offer electric dirt bikes, with Ubco's biggest competition coming from the popular Segway and Kalk.

The FRX1 is incredibly light at just 132 pounds, that's only 60 kgs. That makes it roughly half the weight of traditional dirt bikes. However, Ubco claims that even though it's lightweight, it packs some serious power. The FRX1 has a liquid-cooled brushless motor onboard that is capable of putting out 15kW of power.

This basically translates to 20 horsepower of torque. The FRX1 has a top speed of 50 miles per hour, that's 80 km/h. The bike also features dirt bike suspension with 250mm of travel at the front and rear. The rear shock has both low and high speed compression, spring preload and rebound adjustment. The inverted forks are also fully adjustable. This is a proper Dirt eBike.

The 2.2kWh lithium-ion battery has an estimated range of 100 km, or 62 miles. It'll take 6 hours to charge from empty to full. Furthermore, you can keep track of battery and more using Ubco's accompanying app.

Here you can keep an eye on the speed and range as well. Ubco will keep rolling out updates to the app to easily monitor the FRX1. It is quite pricey though, at \$8,999 and is expected to start shipping in July this year.
