iPhone management software

Tethering still has its advantages

Aditya Madanapalle | aditya@digit.in

A number of iTunes alternatives have cropped up after Apple discontinued the software, that allow you to manage your device more efficiently, and expand its capabilities significantly without the need for jailbreaking. Apple then brought back iTunes for Windows, but by then the alternatives were competing for different features, and many of them have functionality that is worth the premium that they charge. Note that using a third party software with Apple devices is always risky, and use these methods only if you are able to stomach that list. All the steps below are for Windows 10 based PCs and devices with iOS 13.

SPOOF LOCATION WITH DR.FONE

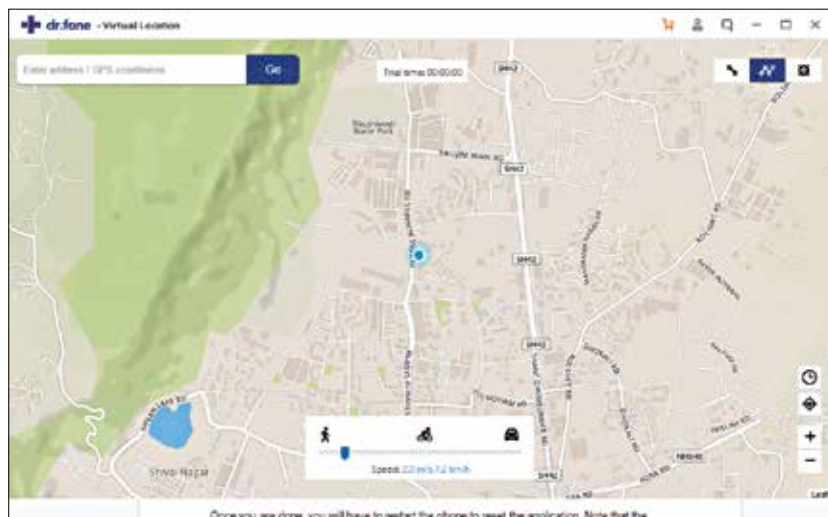

Some applications may use GPS location to allow for some features. One such app that we noticed during the

lockdown was Uno. While the app lets you play 8 player private games, it expects all 8 people to be in the same room. This is enforced by the app by checking the GPS co-ordinates. The particular mode does not even start up if the app is not given the permission to access the co-ordinates. If everyone who wants to play together are at different locations, then location spoofing

is required to allow everyone to play. This is where dr.fone comes in. You will require to connect the device to the PC to do this, and keep it connected for the duration of the spoofing.

Start up the app and click on virtual location, and just select the teleport mode. While you can search within the app and navigate to the location, the base map is neither Apple nor Google, but some other provider who does not seem to have given the accurate names for Indian places. There is a way around this though. Simply go to Google Maps, and zoom in on the location that you want to be located at. Right click and click on What's Here. The search window will now have the latitude and longitude, which should be a pair of numbers like 19.221034, 72.956895. Copy this into dr.fone, and you will be teleported to that location. Now you can start any app on the device, and they will think that you are at that location.

One of the great things about the app is that you can also make it appear as if you are moving in real time, along with control for timing the movement. This is done through entering waypoints, and then moving through them. Dr. fone will move directly between the waypoints in a straight line. To follow the roads you will have to set multiple waypoints that track the roads. This movement can then be used natively in features of apps as if you are actually there, such as sharing the WhatsApp live location, checking in on Facebook, or putting up a location story on Instagram.

Changing the location in dr.fone
