

new object without having to bring up a window for transforming it. Create a cube by clicking on the cube icon along the toolbar on the top. On the right panel, there is a Transform window with the Location, Rotation and Scale options. Make sure all the Location and Rotation values are set to 0, and change the Scale values for either the X axis from 0 to 4. Then, create a new cylinder from the top toolbar. In the Transform field, change the Z value to 1.8. Change the scale transform values for the X and Y axis to 0.3. The idea is to have tall narrow cylinders. In the right panel, click on the tiny grey spanner to select the modifiers. Click Add modifiers, and select Bevel from the list, which is one of the purple icons. You can change the extent of the bevel according to your preferences. Then, select the cube that you created, then Add modifiers and select Boolean from the list. Make sure the boolean operation selected is Difference. Select the eyedropper tool under objects, and select the cylinder with the bevel. Now, click Apply. Unlike other 3D editing software, the object that is carved out from the parent object is not removed. Only the mesh of the parent changes, and the daughter object is freed to be used for another boolean operation. Select the cube, and go back to the transform panel, and change the Rotation X value to -90. You can now see that the top face of the cube has a single hole in it. Now create more cylinders for the other holes. Once the cube has all the holes, the cylinders can be deleted. Indian 4 sided dice have 1,2,4,6 faces or 1,3,5,6 faces. A similar approach can be used to make traditional tokens, which are a sphere attached

to a tiny sphere on a top through a Union boolean operation, and a cube cut away from the bottom through a Difference Union operation.

EXPORTING A UV MAP

A UV map allows you to create or modify the texture on an object. What UV mapping does is give a set of coordinates, along the U and V axes as the XYZ axes are already used for the 3D object. These coordinates

the 3D object that you have. For our token, we just used the disc at the bottom, but there are ways to slice open the UV map in many ways. Once you have selected a circle, or gone around the object in any direction, click on the blue box with red edges, that says Mark Seam. What this does is inform the software where to cut open the map. Click on unwrap. Then go to the UV menu, and select Export UV Layout. This will give you a layout

Create boolean objects in Bforartists.

correspond to an image. Whatever is drawn on that image in 2D, appears on the object in 3D. It is very easy to create a UV map in Bforartists. Select the object, then go to UV Editing panel along the menu. You should get a default UV map, but it is very likely to have overlapping sections. What this means is that the same portions on a 2D object correspond to multiple locations on the 3D object. You have to find a way to unwrap the UV map, so that there are no overlapping regions. Once you have created a UV map, select an edge on the 3D object. This edge depends on the geometry of

for the unwrap, and can be used as an overlay or underlay to paint on another layer that can be imported as the image texture. Now go to the Shading menu and go to Add>Texture>Image Texture. This will give you a box that you can place anywhere on the screen. Click on Colour and connect it to the Base Colour field in the green Project BSDF box. Click in the Image Texture node, select or import the image you want to map, to apply the texture. If all of this seems too labour intensive, you can simply import the obj file into Paint 3D on Windows 10 and directly paint on it.
