WORKSHOP

select the ISO sensitivity of the sensor. These are the same controls you would get on a DSLR, with the only exception of being able to change the aperture value. Unfortunately, smartphone lenses have a fixed aperture and therefore, it is the one setting that cannot be changed. Some Samsung smartphones do sport dual-aperture, but even that is nothing like the flexibility offered by DSLR lenses, going from f/1.4 to f/16. We have already talked about how not all smartphones may feature all the settings that make up Pro Mode, so let's take a look at some of the popular phones, what settings they offer and how best to use them.

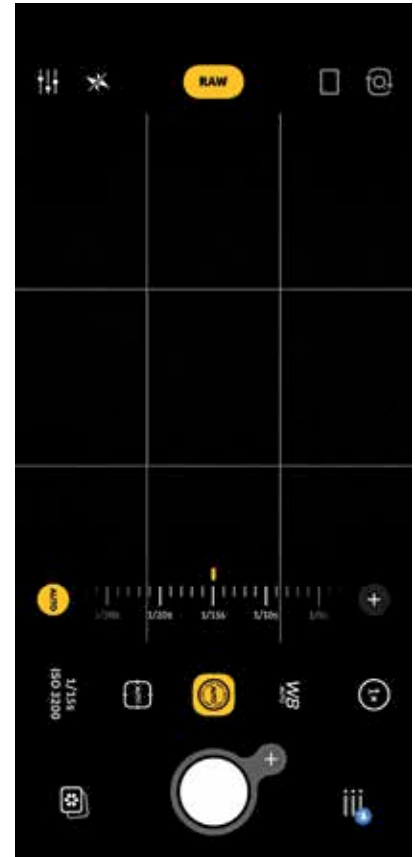

HUAWEI P30 PRO

Perhaps the most exciting smartphone camera for 2019, the Huawei P30 Pro features a triple camera setup, with a unique 40 megapixel RYYB sensor for the primary camera, an 8 megapixel camera with a 125mm lens and a 20 megapixel ultrawide camera with a 16mm field of view. The Huawei P30 Pro also offers one of the most versa-

tile Pro modes in the industry. Each of the three cameras is accessible in entirety. You get the full gamut of controls here, shutter speed control, AF control, custom white balance, manual ISO settings and, of course, RAW Capture. You get all these settings for all three cameras, making the Huawei P30 Pro one of the very few Android smartphones that do. The resolution of the RAW files is native to that of the sensors, so you know you are getting a true, non-manipulated file. Most Android smartphones either do not allow RAW output from one lens or the other or would often only allow a lower resolution RAW output. The Huawei P30 Pro's Pro mode interface is easy to work with, although the setting for RAW capture is accessible only through the settings menu. Additionally, there is a weird bug in the software where if you select the 40MP capture resolution, you won't be able to switch between the three cameras. So, keep the capture resolution to the default 10MP and everything should be fine. The Huawei P30 Pro's Pro mode offers the flexibility of leaving certain settings on auto. For example, if you are trying to shoot light trails from cars, you would have to lower the shutter speed and also lock the ISO at a low level, but you could leave the white balance setting on auto. Similarly, if you are shooting a nightscape, just lock the ISO to a suitably low level such as ISO 800, and the shutter speed on auto. The camera would automatically use a slow enough shutter speed to get the right exposure.

APPLE IPHONE 11 PRO

No article about smartphone photography would ever be complete without the mention of the world's most popular camera. The iPhone's default camera app never offered a manual mode, but that doesn't mean Apple doesn't want users to have control over their images. While the camera app may not have a manual mode, Apple has allowed developers full access to the ISP so that they can develop professional grade camera apps. Apps like Halide and Camera+ 2 are super popular amongst those who

like to have more control over the iPhone camera's output. For those using Halide, you get access to all essential controls we have mentioned before on all three cameras. However, RAW capture is only available on the regular and the telephoto camera. Also, the wide-angle lens does not offer the ability to select a focus point since the module does not feature an AF motor. While Halide allows you to choose your settings in the more traditional manner, Camera+ 2 takes an incredibly unique approach to manual control. The app allows you to select two points on the screen; one for focus and the other for metering. By providing these simple tap-to-set controls, it makes shooting with manual control a lot less intimidating. For those who are used to sliders and numbers, do not worry, Camera+ 2 offers that too. One of the best things about the iPhone happens to be the fact that whether you have the latest iPhone 11 Pro or even an older model like an iPhone 8, the manual controls via third party apps will still be available.
