T

he technology industry thrives due to the innovation of seemingly outlandish ideas that may one

day become a reality. Due to this, unfulfilled promises have almost become the norm. Tech companies imagine the distant future and pitch us what would seem like the definitive image of the next generation of technology. However, a lot of these technologies, as promising as they may seem at the inception or even after years of development, do not really reach the lofty expectations that they were geared to match or surpass. Futurists and technology specialists have had high hopes from various different technologies, and have often used the year 2020 as a checkpoint for them. Unfortunately, we are living in the year 2020 now and these high hopes haven't been lived up to (as of yet) by some of the technologies we will list in this article. Let's look into some promising technologies that failed to live up to the lofty expectations most of us had.

VIRTUAL REALITY

At some point in our lives, most of us have been transfixed by the idea of a

technology that could transport us to another world. VR (Virtual Reality) was hailed as being the bridge between that fantasy and reality. However, most people who have experienced VR, have inevitably been let down by the actual experience of the system. Especially now, during a global pandemic where

the world is self-isolating, it would be the best time to delve into the world of VR to stray away from obsessive doom surfing. While VR systems today have definitely improved technically over the years with realistic graphics, haptic feedback systems, and motion capture, it is still not the fully immersive experience sci-fi films have made us expect. One that transports you completely to another world, unrestricted by cord tangles, the bulky headset, and real world obstacles. Also, outside of gaming, there's very limited content

out there for VR headsets. Additionally, the thought of watching films in a VR headset for an hour and a half to even three whole hours at times, is frankly, cumbersome. Aside from that, many users have complained feeling claustrophobic and queasy while donning these contraptions. The truth is, until VR equipment is shrunk down considerably and perfected to the point of full immersion, the technology will most probably remain an expensive niche and elude mass adoption.

SMARTPHONES

Okay, hear us out. It is true that smartphones have changed the lives of users but in some ways, they haven't managed to keep up with people's expectations of what the future of smartphones could hold. In fact, technologists often opine that smartphone innovation is slowing down or becoming too predictable. Glass and metal 'sandwiches' have been around for years now and it seems like every passing year the smartphone manufacturers are only bumping up the specs but are still staying relatively in familiar territory. While the foldable phones (Samsung Galaxy Fold, Motorola Razr) have circumvented these claims, the
