

existing controls in games. Users can even create additional controls for games that do not actually exist. There are tons of settings that can be fine tuned in the advanced game controls settings. To create new keyboard controls, start the game of your choice in BlueStacks and click on the keyboard icon on the sidebar to launch the Advanced controls panel. Now, from the Game Controls window, you can add custom controls to the game by simply dragging and dropping them onto the screen in appropriate locations. To assign keys and get into more granular controls of the buttons, right-click on the button icon that you have dragged onto the screen. After this, click on the Save Changes button.

You can add an array of controls including a simple button, a repeated tap button, a D-pad, an aim button, a zoom button, a MOBA skill pad, swipe actions, a free look button, a tilt button, and finally, a script button. These controls can really alleviate your gaming experience and allow you to perform some complicated manoeuvres by simply reassigning them to a simple button. For example, you can map the 'repeated tap' button to the action of running in PUBG Mobile. So, you can now run by tapping a button (pushing one key) once instead of the standard swiping up and holding the joystick in that position to run. On the other hand, the script button allows users to create their own customised scripts to trigger a sequence of actions in a game by pressing a single key.

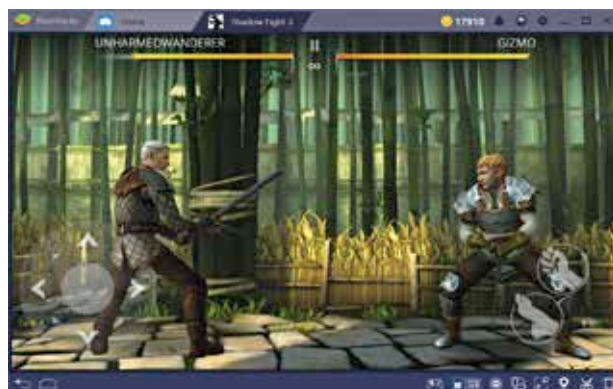

Add advanced controls which simply don't exist in games!

### **IMPORT AND EXPORT GAME CONTROLS**

If you want to import a game's custom controls, that you have created, to another game, the process is actually quite simple on BlueStacks. This is particularly useful if you usually play genre-specific games that have similar controls – say PUBG Mobile and Call of Duty Mobile. The controls you have spent hours creating, tweaking, and

perfecting on one these Battle Royale games can be easily imported to the other. Then, you can simply start up the game and get right into it with your preferred setup. You can also share your customised controls with your friends or other gamers you know, in this manner.

First, launch the game that you will be exporting the controls out of. Next, right-click on the keyboard button in the sidebar or the lower bar. Now, you will enter the advanced game controls tab. At the bottom, find 'More' and click on it. Then select 'Export'. Choose a location on your PC to save the controls and then hit 'Save'. Note: Don't change the name of the file when you are saving it. Now, you can share this file with your friends or simply import them yourself onto another game. To import the saved controls, launch the game you want to import the controls into and right-click on the keyboard button, as mentioned above. Click on 'More' at the bottom of the screen and choose 'Import'. Click 'Continue' on the disclaimer that pops up. Select the file from your PC that houses the keyboard controls and click 'Open'. That's it! The existing keyboard controls

Exporting the BlueStacks custom controls from Shadow Fight 3

of the game will be replaced by the controls that have been imported.

### **ROOTING BLUESTACKS**

To gain access to rooted apps on BlueStacks, you will have to root the emulator itself. Unlike some other game emulators, rooted Android apps are not supported on BlueStacks, so to access them on PC, you will need to root BlueStacks. If you've used BlueStacks before, uninstall the emulator and install it once again. Once you've got that out of the way, you will need to install the APK file of another app on BlueStacks itself which actually lets you root the emulator – BS Tweaker (<https://digit.in/BSTweaker>).

Now, extract and install BS Tweaker. Next, run BS Tweaker as an administrator. Once you've done this, BlueStacks will open and you will see various tabs on the top of the screen. Click on the Main Tab and then click on 'Force Kill BS' on the right-hand side of your screen. Soon after this, both BlueStacks and ADB indicators on the top right of the screen will turn red, which means they have been temporarily disabled. Head over to the Root Tab, and then click on 'Unlock'. Now, simply go back to the Main tab and click on 'Start BS'. Both BlueStacks and ADB indicators will turn green again.

Next, head over to the Root tab yet again and click on 'Patch'. At this point, you can choose to install SuperSU and update SU binary as well. Now, restart the BlueStacks app on your PC and it should be rooted.
