A Wi-Fi printer was the least of Agent001's worries, or so he thought

ou don't need me to tell you that the whole Work-From-Home phenomenon became common-

place only after Covid-19 came onto the scene. I know that's a rather callous way to talk about one of the worst diseases to affect mankind but it's already been four months since we started working from home and at some point, things have to

A little while ago, a colleague of mine reached out to me regarding his home printer. It was an HP Deskjet 5085 printer, one of those with the touchscreen as well as Wi-Fi connectivity. Apparently, this thing had stopped talking to the Wi-Fi router and couldn't be accessed by anyone on the network. He tried opening the 'Wireless Settings' tab on the device menu to search for the Wi-Fi SSID again but all it would do

methods and we'd have to go deeper into the problem.

Obviously, the router is working fine and it must be the printer that's at fault because all the other devices at his home were working just fine and could access the internet. It was just the printer that was acting funny. So, the first step was to plug the device in to the computer with the USB cable and use the HP Smart software to troubleshoot and see if anything could be done. Didn't work. The device had been switched off and turned back on multiple times by now, so the old trick of "Have your turned it off and on again" was already attempted and it didn't bear any favourable results.

Printers don't have a standard mechanism of resetting. It's not just between manufacturers but even within the same manufacturer, there are different methods of resetting printers. Since we're dealing with HP, let's use HP's printers as examples. Most printers have a 'Cancel' and 'Resume' button. In some cases, you can switch the printer off completely and then switch it on by keeping the resume button pressed. Sometimes you have to keep the 'Resume' and 'Cancel' button pressed down at the same time in order to reset the printer. And in certain cases, you even have to pull the power cable

normalise. One of the things that happened thanks to the whole WFH shift was that more and more people started getting laptops, Wi-Fi routers and printers, and that too, the better kind. Not the cheapo "five bucks a pop" routers. So a lot of the queries we've been getting from our readers and even our friends and family happen to be centered around laptops, printers and routers.

was keep the progress bar running for a while before giving up. And it wasn't as if it was averse to this one Wi-Fi router while spotting all the other Wi-Fi signals in the area. It simply wouldn't spot anything at all. The issue sounds kinda simple and my colleague is also well-versed with stuff so if he was reaching out to me, then I bet he'd must have tried all the basic troubleshooting
