lot of customizability, don't look any further.

- GDM: If you have ever used Ubuntu, you would have used GDM. Gnome Display Manager is an extremely popular DE and a lot of Linux distros ship GDM as default DE. User-friendly, a great DE for beginners.
- KDE Plasma: The most resource intensive among all, KDE Plasma provides the most amount of features and options to tweak the settings to your desires. KDE Plasma 5 means eye candy galore! If you have a computer with powerful enough specs KDE is the best choice.
- LXDE: You want extremely minimal DE? If you can compromise on eye candy, if you are lazy, if you are running Linux on a 2008 toaster, LXDE is the dream.

A lot of other DE's are available so don't forget to browse through them if these don't suit your needs. And keep in mind, you might not even need a DE! A fully functional workstation can be made without having a DE and most of the very beautiful riced desktop doesn't have one. A standalone file manager, the window manager is more than enough. This brings us to the next section.

Window Manager:

Okay this is the most important part and requires the most attention from any ricer. Before jumping at the options, let's talk about window managers (WMs) and their types.

Linux distros ship with X Window System for drawing the desktop over your screen and X.org Server is the most common implementation of it. But because of X.org's modular design, it doesn't manage windows but instead, it depends on a piece of software called a window manager or WM. WM moves, resizes, responds to user input and all the things you usually do with desktop windows. Now WMs are of three types:

- Stacking or floating WMs: These are the classic window managers,

like the one you must've encountered in Windows. The windows can be stacked on top of each other as the name suggests, basically acting like pieces of paper on a desk.

- Compositing WMs: Also called compositor, they create a buffer for each window and assign them this buffer. Then the result is written to the display memory. This allows transparency in windows. Crashes due to repainting are less frequent than stacking WMs.

Author's sombre, poor-man's conky theme

- Tiling WMs: These tile windows side-by-side with already opened windows. So say if you open a new window, it'll automatically be placed beside the existing window. Some perform static tiling, where the number of open windows is fixed while some do dynamic

tiling whereas the windows are opened, earlier windows are resized to make space for the new ones and so on.

- Dynamic WMs: Combining the features of tiling and stacking, these WMs can toggle between the modes according to the user preference.

So now that we have covered the whys and the basic concepts, it's time to get dirty with real world applications and how you can create an aesthetic desktop.

THE EYE CANDY

"But but, which window manager? And how all of them have nice system stats updating each second and music visualizer with RGB modes?!" Patience, young ricer. For we unfold the many secrets of the best rice builds out there. Let's begin.

Resource Monitor:

An application, with a size of just under 5MB, is the favourite system monitor among the masses. Enter Conky. A free, light-weight system monitor for X (the X Window System we talked about above) that will display whatever info there is to display about your system. The output of any Linux command can be used as a field in the Conky window. It can receive data streams from popular music players to show status directly in the system monitor window. And so much more, that a conky guide is beyond the scope of this article.

Window Manager:

First, let's revisit something we talked about, efficiency. Most rice builds include a tiling window manager because that way you'll be aware of the content on your screen at all times. As a result, most tiling managers use keyboard shortcuts to cycle through windows, open applications, close windows and other things. Hence, your hands will never leave the keyboard to reach for the mouse. Efficient? Subjective. But if you have a big screen or a multi-screen setup, this
