i3 running Vim, scrot and a terminal based file manager (notice not gaps between windows, i3-gaps fix this)

will help you for sure. Here's a list of the best window manager according to the ricing community:

- **Awesome:** A very powerful tiling manager, awesome is an awesome(sorry bad-pun police) window manager and powerful at the same time. Even though it looks bad straight out of the box, with LUA support and enough time spent on programming the configuration file, awesome-wm can turn out pretty good.
- **Dwm:** Ok newbies, beware. According to themselves, they want to "keep the user base small and elitist", hence there's no simple configuration file but a C header file that you need to recompile the WM yourself. But if you know C and are willing to get down and dirty with the source code, you can try your hand at this.

- **i3wm:** No doubt this is the most popular tiling window manager, with ease of use it provides. A fork of wmii(window manager improved 2) it was created to solve wmii's haphazard code and documentation problems. Appropriate for beginners and veterans alike, this should ideally be your first tiling WM. While itself a fork, there's a popular fork of i3 itself called i3-gaps, which have additional features, such as gaps between the windows, smart borders, etc.
- **Compiz:** Developed since 2006 and actively maintained, Compiz is a very popular compositing window manager and is known to provide a lot of features and

functionalities with many interesting features. It uses OpenGL, hence if the graphics drivers are not set up properly on your Linux, compiz can cause problems.

The first three WMs were dynamic WMs, letting you choose between stacking or tiling modes. There are several standalone stacking and til-

ing WMs to choose from. You'll figure those out once you get into ricing.

Status Bar:

Remember the chunky blue taskbar from the XP days? The very limited taskbar served a few functions, but overall customizability was still restricted. But hey at least it came in blue, silver and olive green color! But the past is past. You can have as many status bars now as you want. Go ahead and put one for each edge of your screen. Or more. It's your build after all.

The favorite among masses is absolutely Polybar. According to it's github "Polybar aims to help users build beautiful and highly customizable status bars for desktop environments." And boy does it succeed. With simple bash scripting, Polybar gives you the traditional services like time, date, open application windows but adds on top with features like

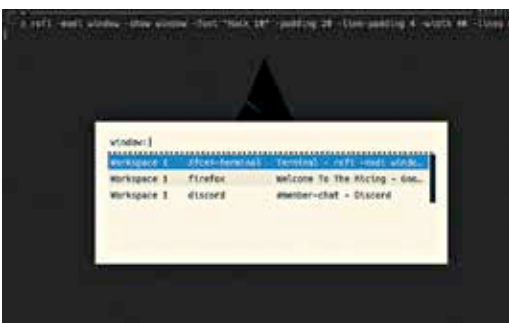

Polybar-5 theme by adi1090x

backlight control, music control, weather info, network speed and then some. This is going to be controversial, but we are going to go ahead and say it, Polybar is like conky, but for status bars. If that makes sense. If you have installed rofi (an awesome window switcher and dmenu replacement) you can create custom windows that can be opened using buttons on Polybar. It's a swiss knife of status bar.

Vanity:

At this point, you would have a working build. But to give everything an extra amount of oomph, one or two final touches are required. Linux users
