

Profitable Python

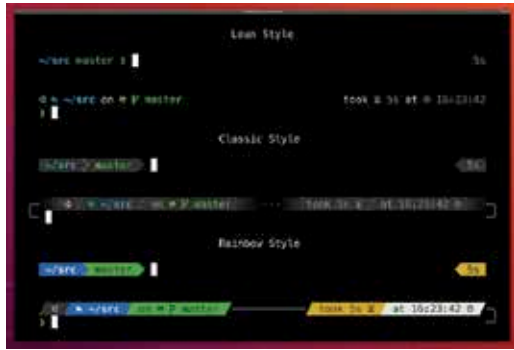

A podcast hosted by Ben McNeill for Python developers who want to take their skills to the next level <https://digit.in/aug20-75>

VMware update

A new VMware load balancer update distributes workloads across networks to ensure reliability <https://digit.in/aug20-76>

spend most of their time on a terminal window and as a result, it's quite natural to have a terminal that'll look and feel nice to work on. Now even though most people use the word terminal and shell interchangeably, they are quite different. Shell is what

P10k prompt styles

runs inside the terminal and terminal is actually a terminal emulator which, as the name suggests, emulates a visual terminal in some other display device. But we aren't focusing on the technical aspects, rather the visual ones. And the good news is, you can customize both.

When it comes to customizing the shell, the major choice is zsh. Z Shell was initially released 30 years ago, but is still maintained profusely. It is an extended Bourne shell with some borrowed features from other shells like bash, ksh and tcsh. Along with it's plugin oh-my-zsh, your shell can turn into a real powerhouse. With improved command completion and auto-suggestion according to previous commands in history, your terminal productivity will be more than ever. Oh and the visuals are nothing like you have ever seen. Most used theme with zsh is the Powerlevel10k which is just a beauty with speed. You can install zsh using your distro's package manager.

Now if you setup the above shell configuration, you'll need appropriate fonts. There are lot's of fonts available but zsh uses icons/glyphs (to represent clock, status, folder structure etc) and those are hard to find. An awesome GitHub repo solves

all the problem, which has fonts with over 3000 glyphs.

Now that you have this done, it's time to browse files on your local storage. Regarding file managers, you have two choices. Either to opt for one which is text/terminal based and you'll need a keyboard to navigate the file structure, or a visual based one where you can use your mouse. No matter your choice, the desired result should be a lightweight file manager, fulfilling your needs. But remember navigating using a text based file manager will take some hands on practice till it eases in. If opting for text based, you can go for

Midnight Commander or ranger,

both are lightweight and will fit in with your build. Visual applications, as the name suggests, are usually resource intensive, but for beginners Thunar is a very lightweight FM. It is the default file manager of XFCE DE but can be installed standalone from distro's repository. Others in this category are janky and heavy applications *Window Explorer flashbacks*.

Of course you are going to show off your build when it's complete. But every build portfolio is incomplete without a terminal window showing system info in it. Neofetch or screenfetch does a pretty sweet job doing that. They throw in the distro logo also for extra sass. To top it off, pipe the output to lolcat (rainbow coloring utility) to give a dash of color.

Since we reached the show off part, we assume that by this point in the guide you have a full fledged riced-up Linux build. Go ahead and find reddit communities to show off your creation. Just a word about the

choices we have presented, though there are a lot of options available for each category, we provided the choices which are lightest on the system, because traditionally riced builds are supposed to be as light as possible. If you have a powerful PC, you can venture out of these bounds and experiment on your own.

Ricing is a concept where only veteran Linux users dwell in, but we felt the community needs more eager brains and eager brains produce innovative results. Hope this guide sparked a desire to tinker more with your systems and get the creative juices flowing.

The interest towards ricing might even generate a new wave of people willing to try their hands on Linux. A whole generation of computer users shy away from Linux due to the

Author's system info. Without and with lolcat

mythical hardships in its usage and elitism in the community. As Linux lovers ourselves, this our attempt to turn the tides. Linux can do what Windows can and much more, as you just witnessed (okay maybe it can't run Valorant and Apex Legends, but CSGO still runs and that's where our heart lives). We hope by the end of this article, some of you have a build that you can be proud of. And once you get started, don't forget to send us your builds. Happy Ricing! 🍷
