

reduces data consumption. You can save pages for offline browsing. What all of this means is that by default, Chrome is like the lite versions of other browsers such as Opera or Firefox. Of course, all of Google's services work very well with the browser, but not as well as the dedicated apps such as Drive, Docs, Sheets or Keep. If you want to reduce the number of apps you have installed and still use Google services through the mobile device, then Google Chrome is the way to go.

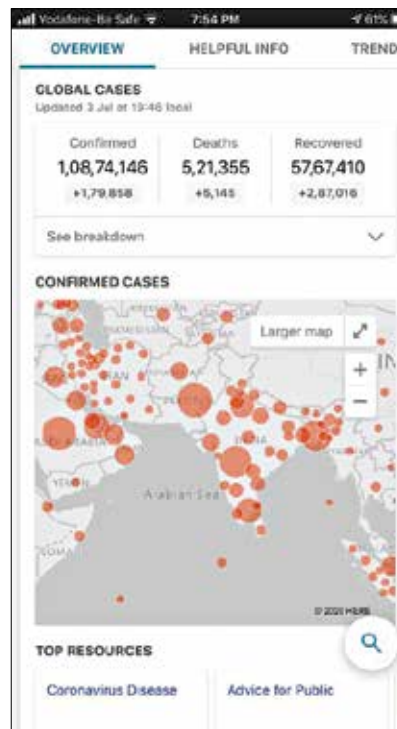

Another powerful feature is easy translation of all web pages using Google Translate. Like most other mobile browsers, Google Chrome also syncs easily with the PC version, allowing you to sync tabs, bookmarks and passwords. The cutting edge features are available in Chrome Beta, and the unstable version is called Canary, which is not nightly but updates a few times every week.

Edge

Although coming from a major tech company, Edge can be considered as an alternative browser because of the negative associations with Internet Explorer. Edge is actually surprisingly good, and for those who have tried it, the experience with Bing is better than Google. For some reason Microsoft claims to have gamified the use of the search engine, and that it gives you rewards for using Bing, they have just become that desperate now. However, we use Bing a lot and could not find these rewards. Bing search is actually the strongest feature in the browser, as it shows you all the information you need at a glance, creating boxes of the relevant contents. For example, searching for "Corona" gives you stats of the confirmed cases, deaths and recoveries in the city, state, country and global levels. It also shows a map of the pandemic, and resources to get help. Then there is a box with news videos. The entire activity of search has been converted into an experience, and the best thing is, that the experience can directly be embedded. At the same time, the search does not give you what you want, for example a search for "Corona Go" will deliver the same Corona widget. Most of the time though, the widgets work beautifully. For example, if you search "Guardians of the Galaxy 2" you get a hotstar link first, a synopsis from the Wikipedia article, a

soundtrack listing, critic reviews, a list of cast and characters, images, the IMDB link, and news related to the movie. In the end there is a handy list of additional searches. Seriously, the search experience is unparalleled.

Edge is almost as militant as Firefox when it comes to privacy, and takes measures to prevent tracking of your surfing habits. The tracking prevention tech is enabled by default, just like all Firefox browsers. There is also an integrated Ad Blocker, which is not turned on by default. The private mode does not save history or passwords.

The search results in Microsoft Edge

Dolphin

This is a strange little browser that has been built from the ground up for touchscreens, and does not have a desktop legacy behind it like most of the other browsers in the list. In the early days of smartphones, around 2010, Dolphin was the go-to browser for a superior surfing experience on smartphones. It won a lot of awards back in the day, but has since then lost its lead. Dolphin is still heavily focused on delivering a great user experience on touchscreens.

That means that there are a lot of features that have been included keeping mobile devices in mind. One of these is the integrated voice search, but

such a feature is currently present on other browsers as well. The differentiating feature here is the ability to create custom gestures to quickly open up web sites. For example, you can trace a "D" on the screen to fire up Digit.in. The speed dial is also very easy to use. Swiping switches between tabs, which is faster than the two taps required on most other browsers. The laser focus on usability on touchscreens is the best when it comes to Android, but you are better off using Opera Touch on iOS.

The browser also allows you to download videos for offline viewing. If you like to customise what little of the browser is visible during surfing, then there are options to add background images and tweak the colours, as well as themes. There are some other features for smartphones, such as a battery saving mode, a speed booster, and the ability to save web pages as PDF files.

JioBrowser

The browser is pushy about some content (mostly news and videos), but has some nifty little features. There is an integrated QR scanner to quickly access links, and a voice search feature as well. The browser also shows live cricket scores in a ticker, and actually has a quick search suggestion feature that is faster than Google. The quick search feature works really well when it does, but is otherwise useless. Users can download content through the integrated download manager, and even schedule downloads. All these extra features show that the browser has really been made keeping in mind the browsing habits of Indians, and the localisation goes beyond just supporting more languages. Another feature that is helpful for older people is that the browser allows you to zoom into content on web pages. The browser is made with an entirely mobile experience in mind though, and lacks the features for using it in tandem with a computer, such as exporting or importing bookmarks sending files from the device to a PC. Compared to all the other browsers on the list, it is also a little glitchy. That said, the user interface is very simple to use, and accessing even the advanced features is made easy. The expected features such as private browsing and night mode are there. There is no ad blocker though.
