

eMarket for farmers

Agri10x is an AI, blockchain and IoT powered eMarketplace for farmers, that is used around the world. <http://dgit.in/sep20-43>

Paytm Mall data breach

Hackers claim they got unrestricted access to the paytm mall database, but the firm denies any breach. <http://dgit.in/sep20-44>

RTX or RDNA?

With the next generation of graphics cards around the corner, Agent001 has a few things to say about upgrading.

Agent001 | agent001@dgit.in

N

VIDIA's next generation RTX 30 series of graphics cards will have already been announced by the

time you're reading this but the cards won't be available for purchase until mid-September and that's a good thing. The upcoming Ampere graphics cards are expected to have a 30-35 per cent increment in performance over the current gen Turing cards, especially

NVIDIA charged a ridiculous price premium for all graphics cards and this premium was for practically nothing since there were barely any RTX games in the market.

It wasn't long before NVIDIA made RTX accessible to the GTX cards as well. The performance of RTX cards was still better when ray-tracing was enabled but wide-scale adoption was still years away. Two years have passed since the introduction of the RTX 20

DXR has finally made hardware-accelerated ray-tracing a viable concept to include in video games. And game developers have already started incorporating them, especially since the upcoming PS5 and Xbox Series X consoles have adopted the same.

The leaks around the NVIDIA cards have been all over the place. There's supposedly an RTX 3090 with 24 GB of VRAM, followed by an RTX 3080 with 10 GB of VRAM and then there's an RTX 3070 with 8 GB of VRAM. The difference in VRAM capacity for the RTX 3090 and RTX 3080 indicate room for additional graphics cards. Some rumours indicate that there might be an RTX 3080 with 20 GB of VRAM. We don't know if this will be an RTX 3080 Ti or an RTX 3080 Super. NVIDIA's GeForce nomenclature has gotten unnecessarily complex. And the reason for that is AMD. RDNA2 is AMD's successor to the RDNA micro-architecture that's powering their RX 5000 series. The RX 5700 XT, 5700, 5600 XT, 5600 and 5500 XT are the reason why we have the NVIDIA "Super" cards. Up until the introduction of these cards, NVIDIA was following the old Ti and Non-Ti nomenclature. The RX 5000 cards outperformed NVIDIA's existing mid-range stack or were very close, necessitating the introduction of the Super cards. With the upcoming RTX 30 series, we're seeing similar signs.

when it comes to hardware-accelerated ray-tracing. NVIDIA took a massive leap of faith with the RTX 20 series by incorporating a whole new paradigm but it was way too early. Very few games made use of RTX and the ones that did, ended up bringing graphics cards to a halt with their intensive compute. It took a long time before the RTX games were optimised in any way. Needless to say, there weren't a lot of takers for the new RTX cards since

series of graphics cards and a lot has changed. Console manufacturers, both Sony and Microsoft, have incorporated custom AMD Radeon RDNA2 GPUs which support Microsoft's DXR (DirectX Raytracing). This was good news since a Microsoft IP is more likely to be accepted by developers rather than something by NVIDIA since NVIDIA would prefer to limit it to just their hardware. With a more open approach and industry adoption, Microsoft's
