

Nanotechnology, nano-materials and nano-science is something Digit has been mentioning for close to two decades now, and those of you who have been along for the ride for the past 20 years will know it's a staple in all futuristic predictions by everyone from the world's most renowned futurists to us lowly writers. So what makes us want to write about nanotechnology once again in 2020?

To start with, it's 2020 – a year when a nano-scale virus brought the world to its collective knees, killing a million people, and destroying global economies and life as we know it... But SARS-nCOV2 aside, 2020 was a popular year for futuristic predictions for over 40 years – especially in the first decade of the new millennium. It just makes sense for us to stop and take stock of the whole nano-hype that we've been hearing for decades, and to see, not just how far we have come, but to also look at major breakthroughs that have happened recently, and to understand how it affects our future.
