No, this is not an ad. Research has shown that fine-tuning stem cell metabolism prevents hair loss. <http://digit.in/oct20-84>

Steam power

A small number of enthusiasts around the world continue to push the limits of steam engines

here was no single point in time when the steam engine was “invented”. In the first century AD,

Hero of Alexandria (that was the mathematician’s name) described an Aelopile, also known as Hero’s Engine, a spin turbine that rotated when the steam contained within it was heated. It simply had two outlet nozzles for the steam pointed in opposite directions. This however was a device of little practical importance. The first real use of steam power was by

Thomas Savery in 1698, who came up with a process of using steam power to pump water from coal mines. Before the invention of this pump, water would be drawn up from the mines using a system of ropes, pulleys, buckets and horses. Savery’s invention was cheaper and more energy efficient (no need to feed the horses). Although the pumps worked only in shallow depths, they were just practical enough to find widespread use. Another Englishman, Thomas Newcomen developed a similar engine at around the same time, called the atmospheric engine. It used a piston that actively pumped water, instead of a chamber that used the vacuum created by condensation to draw up water. The patent awarded to Savery meant that Newcomen had a hard time marketing his atmospheric engine, which was designed for the same purpose of drawing water from coal mines. Newcomen was forced to start a company with Savery. In 1763, James Watt improved on the design by Newcomen, and found a way to move

the piston back and forth while driving a wheel. This improved design started off the industrial revolution. From mining, the engines spread to other industries, including manufacturing, construction, excavation, metal working, textiles, the bellows for blast furnaces, and other factories. In fact, steam power allowed for the building of bigger and more powerful steam engines. These massive steam engines were like stationary locomotives on the factory floors. Despite fossil fuels and electricity taking over, the steam turbine, a more advanced version of the steam engine, is still used to generate a significant portion of the world’s supply of electricity.

CARS

Steam powered cars were only viable for manufacturing over a short window of time when the steam technologies were refined enough for rolling out at scale, and before the development of the internal combustion engine. This was roughly between 1850 to 1915. A number of
