GEEK-KEY

the world from humanity. Similar to the creation of GLaDOS, Helios also assimilates JC Denton into itself.

MULTIVAC

Multivac, a mainframe computer used by Asimov in a number of his books, shows up with different capabilities and configurations, depending on the time period in that particular work of fiction. Multivac is what would happen if networking between computers was strong enough from the onset, that the processing power would never be distributed to individual users, and cloud computing could take off from the get go. Everyone in the world would have access to Multivac, instead of individual computers of their own. Multivac is both the machine and the network, and uses natural language processing to interact with users. Multivac was an inspiration to Clarke's HAL 9000, and is considered its spiritual predecessor.

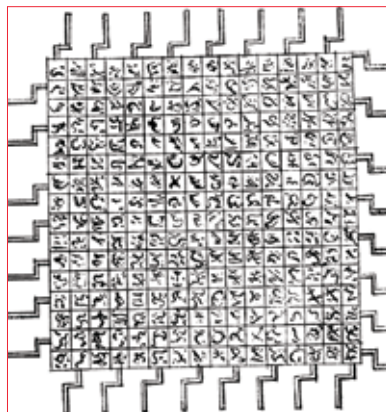

SKYNET

In the Terminator series, Skynet is a supercomputer that uses artificial neural networks. It is designed to be plugged into everything, allowing for the autonomous micromanagement of a large number of interconnected systems, including weapons systems and fighter aircraft. It is a computer with global reach, and when it gains self awareness, humans try to kill it. The machine retaliates by attempting to wipe out humanity instead. For the most part, it succeeds, and then unleashes an army of machines to round up the survivors. In some sort of a strange inverted moebius strip time loop, Skynet is built using the hardware recovered from a robot that it sends back through time to kill the leader of the human resistance, John Connor before he is born.

THE ENGINE

This is one easily the oldest example on the list, and one of the earliest descriptions of computers in fiction. The Engine is a machine from the 1726 book Gulliver's Travels. The computer is essentially an encyclopedia, giving replies to specific questions on all the arts and sciences, allowing an ignoramus to get instant answers to things that they did not know about. The input is a series of handles along the sides of a frame that have to be turned in unison. The output is a matrix of wooden blocks of various sizes and shapes, with paper stuck to their sides, which have words printed on them. When the handles are turned to pose a question, a network of wires between the wooden blocks reorient them in such a manner, as to provide a readable answer.

THE MAGI

The Magi are a trio of supercomputers that are used to control and manage the Evangelions, the giant bionic robots that are used to tackle the angels invading Earth in Neon Genesis: Evangelion. These are "7th generation" organic computers, that are infused with particular aspects of the personality of

their designer, Dr Naoko Akagi. The idea here is that the competing priorities in the three different supercomputers would allow them to come up with an optimum solution, an approach used by adversarial neural networks that are made to fight each other to come to a conclusion. Melchior has the persona of a scientist, Balthasar has the persona of the mother, while Casper has the persona of a woman. The three computer setup is replicated by NERV in multiple sites around the world.

VECTOR SIGMA

Vector Sigma is a supercomputer that exists in the core of the homeplanet of the Transformers, Cybertron. It is a conduit between the sentient machines and their god, Primus. It has many terrible powers. Even the activation key, which is a mere input mechanism, includes a death ray that reduces biological matter to metal. Vector Sigma has a rather

unique architecture in the sense that it is actually connected to other versions of itself across parallel universes. The events in the various Transformers timelines take place in these universes, but one thing is common amongst all of them, Vector Sigma. This network between universes can communicate with each other, through what is known as the Vector Sigma Gesalt. Each incarnation of Vector Sigma within a particular universe is known as a node.
