Gennaris bionic vision system

Researchers at Monash University have created wireless implants which sit directly on the surface of the brain. These implants can allegedly restore vision to the blind. The Gennaris bionic vision system comes with a custom headgear fitted with a

camera and a wireless transmitter. Then you have a vision processor unit and software, and a set of 9x9 millimeter tiles that are implanted into the brain.

The device was first tested on sheep and was found to be successful without any adverse health or side effects. The team is currently looking for funding to increase manufacture and distribution of the implant, and they believe that the next step is using the implant to cure other ailments, such as paralysis.

SkyDrive flying car

Japan's SkyDrive is one of the many flying car projects currently active around the world. However, what sets them apart from the rest is that they've actually managed to successfully carry out a test flight with one person aboard.

In the video that was showcased to reporters, what looks like a motor-cycle with propellers lifts about 2 meters off the ground and hovers in the designated netted area for four minutes. The machine can reportedly fly for about 5-10 minutes currently. The head of SkyDrive, Tomohiro Fukuzawa said he hopes the flying car will be a real-life product by 2023, and that making it safe was his priority. SkyDrive is one of the few of hundreds of flying car projects in the world that have succeeded with a person aboard.

Hannes

A team of orthopedists, industrial designers and patients have worked together with scientists from the Istituto Italiano di Tecnologia, Italy, on an artificial hand named Hannes. What makes Hannes so special you ask? Well, this is a prosthetic hand that can reportedly grip and move like a normal hand, restoring over 90 percent functionality to people with upper-limb amputations. It was designed to accurately replicate the size, weight, appearance, and natural grasping motion of a human hand. This includes natural and adaptable movement, and being able to use different levels of force and speed.

Mimic

Designer Roman Dolzhenko's Mimic Superbike Concept looks like it's been pulled straight out of Tron. This is a very futuristic-looking electric superbike concept with a minimalistic design. The concept was designed in 3DS Max to look extremely photorealistic. Roman's inspiration for the design is very clearly from Tron, and

the classic anime, Akira. So much so that along with a white and chromium black design, there's also flashy, red design to show the Akira influence.

The Mimic features a fully digital dashboard on the front. It's a triangular-shaped display which shows basic data such as speed and battery.

Looking at the bike might give you the impression that the bike will have trouble turning, but the whole front of the bike turns. However, this mechanism isn't too practical right now.
