

multiple cursors, which means that you can put in as many cursors as you want in the document, and then type in such a manner that the inputs show up next to all the cursors. If you need to modify code, or add the same piece of code in multiple places, this is the perfect way to do it. To add another cursor to the document, simply press **ctrl** and click on the location you want the second cursor to be. This process can be repeated till you have the number of cursors that you want. Now you can start typing, and the text will appear wherever there is a cursor.

HIGHLIGHT ALL INSTANCES OF A WORD

This is another incredibly useful trick that allows you to work with large and complex documents. Say you want to find the starts or ends of multiple lists in an HTML document, you can highlight all the instances a tag such as `</ul>` shows up in the document. To do this, position the cursor just before the string that you intend to highlight throughout the document, and press **Alt + F3**. A word of warning for this particular shortcut though. You

```
public void UpdateShockwave()
{
    _shockwave.transform.localPosition = Vector3.Scale(localPosition,(new Vector3(size, size, size)));
    _shockwaveEmitter.color = color;
    _shockwaveEmitter.duration = duration;
    _shockwaveEmitter.durationVariation = duration * 0.1f;
    _shockwaveEmitter.count = 1;
    _shockwaveEmitter.detail = 1;
    _shockwaveEmitter.particleSize = 25f;
    _shockwaveEmitter.sizeVariation = 0f;
    _shockwaveEmitter.velocity = new Vector3(0f, 0f, 0f);
    _shockwaveEmitter.startRadius = 0f;
    _shockwaveEmitter.sizeGrow = 260f;
    _shockwaveEmitter.size = size;
    _shockwaveEmitter.explodeDelayMin = explodeDelayMin;
    _shockwaveEmitter.explodeDelayMax = explodeDelayMax;
    _shockwaveEmitter.renderMode = renderMode;
```

Editing a project using multiple cursors

DUPLICATE LINES

This is yet another time saving nifty little feature. When working with CSS, XML or any other language actually, it might be necessary to duplicate lines. The way Atom lets you do this is actually faster than even **Ctrl + C** and **Ctrl + V**. There are many ways to get this done, but there is only one way that takes the least amount of time and effort. Use the arrow keys on the keyboard to go to the start of the line, then press **Ctrl + Shift + D**. It is also possible to duplicate multiple lines at once, by highlighting all of the lines to be copied then pressing **Ctrl + Shift + D**. This trick also works with the previous multi cursor trick.

do have to remember to be careful while using this shortcut, because you might get too used to it, and in a hurry you just might end up mistyping and press **Alt + F4** instead, and you know what that will do.

USE SNIPPETS

Snippets are small pieces of reusable code that you can customise and introduce into your workflow. All you need to do is type a phrase and hit **tab**, then the piece of code with preset values gets introduced into the document. While there are many packages with preconfigured code, it is really helpful to define and use your own snippets. Using snippet-

pets is something that you must train yourself to use, but once you get familiar with the concept, you again stand to save a considerable amount of time by not having to repeatedly hunt down the same snippets of code and copy pasting them where relevant.

USE PACKAGES

This is the most important tip of all, and what makes Atom so flexible and extensible. Packages are similar to the extensions on Chrome, that allow you to do a lot more with the text editor. There is a package browser within the application that makes it easy to find and install packages. Do note that the more packages you add, the slower the startup of the software is. After installing the packages, you can customise the options for each of the packages as per your preferences. We are going to start off with something that is not really considered best practice, as it is something that you should be doing yourself but Emmet is a package with a bunch of CSS and HTML code snippets that is just incredibly practical and handy. Another popular package is the Tree View, which provides a sidebar to the right that shows a map of the entire document, allowing you to quickly navigate through and find the area of the code that you want to work with. Then there is Pigments, a package that shows the colours that you are using in the code, within the code itself. For example, in CSS `rgb(133,153,0)` gets highlighted in the lime green colour when using Pigments. The git-time-machine package allows you to explore previous versions of the code, and look at a commit at some time in the past, or the commits within a time frame. There are many, many more packages available, explore them and find the right ones for you.
