Mercedes-Benz eScooter

Owning a Mercedes-Benz is a dream for many, lucky for you, Mercedes-Benz' latest could just be your first. The Mercedes-Benz eScooter is a first from the German carmaker. Developed in partnership with Micro Mobility Systems AG, the Mercedes-Benz foldable eScooter runs on a 500W motor, that can push the eScooter to a comfortable 20kmp/h. It has a 7.8Ah battery, which gives it a range of 25km. So at full speed,

you can run the Mercedes-Benz eScooter for roughly a little over an hour. The eScooter has impressive front and rear suspension, with 20cm rubber wheels for good traction on the road, regardless of how bumpy it might be. Additionally, the eScooters steering stand is adjustable, so it can be increased or decreased in height in accordance to the user. The

Mercedes-Benz eScooter weighs in at almost 14kg, and there's a centrally-mounted display where you can see info such as speed, battery level, and mode information. More data can be gained by pairing the eScooter with your smartphone. There are also lights on both the front and back of the scooter. With all those features, they've attempted to make the eScooter as road-ready as possible.

Doggles

The US Army is developing AR goggles for dogs to help them better protect their human guardians. The project, which is funded by the Small Business Innovation Research program, aims to allow soldiers to give dogs specific commands even when they're not in direct line of sight of the dogs.

Stephen Lee, a senior scientist at Army Research Laboratory says, "Augmented reality works differently for dogs than for humans". Unlike with humans, who actively interact with Augmented Reality, with dogs, AR will solely be used to issue commands and give visual cues to the dogs, they will not be interacting with the AR directly.

In order to accomplish this, Command Sight created a prototype device, which includes a pair of goggles to put on the dog, a camera, and a display that fits over the dog's eyes. The display gives the dog visual indicators, or cues, on what to do next. Furthermore, through the goggles, you can also look at and know exactly what the dog is seeing.

In its current state, the goggles still require the dog to remain on a leash since they aren't wireless yet.

Dormio

Sleep trackers are fairly common nowadays. However, sleep trackers that can be used to shape your own dreams? Not so much. Tomas Vega has been working with researchers at the MIT Media Lab to create just that. According to Vega, it works, and to test it, he recorded the Oompa Loompa song from Willy Wonka and the Chocolate Factory, and then instructed Dormio, the device, to play it to him as he began falling asleep. The result? "I started dreaming about being in a chocolate waterfall, surrounded by Oompa Loompas".

Vega tested Dormio on a group of 50 people for a larger sample size, and the results were published this September in the Consciousness and Cognition journal,

suggesting that Dormio could indeed guide people to dream about topics of their own choosing.

Dormio has two parts, the first is an app, and the second is the wearable device itself. It's not your usual wearable, with it attaching to not only your wrist, but also to your forefinger and middle finger. The device monitors heart rate, the position of your fingers and other cues to track sleeping patterns. The app is used to play and record audio. When the user enters the earliest stage of sleep, hypnagogia, Dormio activates. During this stage, the mind is loose, flexible and suggestable according to Dr. Adam Haar Horowitz.
