CD Projekt Red to reveal Cyberpunk 2077 DLC, post-launch; Q1 next year. <https://digit.in/dec20-70>

Finicky RGB

Agent001 goes on a wild goose chase attempting to fix an RGB LED that won't sync with the rest

Agent001 | agent001@digit.in

T

he RGB-fication of PC components has garnered up quite a lot of hate and love in the PC enthusiast

community. Folks do like a little bit of colour but with the fragmentation within the RGB ecosystem, you can either invest in one brand and compromise on quality of individual components or invest in quality components and lose the ability to synchronise all RGB ecosystems. You can't get both easily. For example - Noctua makes some of the best cooling fans in the business but has no RGB elements whereas every other manufacturer has oodles of RGB LEDs packed into their cooling fans but they've compromised on throughput or acoustic performance. So it's either quality or performance when you want to RGB-fy your system. Let's say that you've figured out a way to get the best of both worlds and you've got not only quality but also an aesthetically-pleasing RGB setup. What if, one of the components decides to go off being all wonky, what would you do then? Well, that's the dilemma Agent001 underwent this month.

Referring to myself in the third person feels so odd but you see me do it anyway each month just for the lulz. And because it also makes for a good introduction. Anyways,

coming to the problem at hand. I ended up building a new rig for a friend using components aimed at a media authoring build. We built a nice Threadripper rig and were piling in as much RAM as we could find. My friend wanted a bit of RGB flair so we went with RGB memory and fans that were compatible with the motherboard that we'd chosen. The

build process was smooth, everything fit right without any problems and we went about installing the operating system and all the drivers and software suites.

Having reached a stable state, we decided to play around with the RGB profiles to see what all we could do given our current arrangement and if we could pull off a groovy lighting scheme. It was then that we realised that one LED at the absolute end of one of the RAM sticks was out of sync. While the rest of the LEDs

would light up in purple, this one would be blue and when we used a different colour, it seemed to be out of phase with the rest. The RAM stick and motherboard were from different manufacturers so a conflict between the RGB software is also expected. Although, a software conflict would have effects across all the RAM sticks and not just the one. So a physical

fault is more likely rather than a software fault but we decided to be certain before sending it out for RMA.

We started off by uninstalling the motherboard manufacturer's RGB software and retained the RAM manufacturer's RGB software. As expected, this had no effect and

the RGB on the RAM modules could be controlled properly without any problems. We then updated the firmware on the RAM modules hoping that might solve the problem. Again, we saw no change to the situation and the one LED was still out of sync with the rest on the stick. We then swapped the RAM sticks on the motherboard to see if that could help. The faulty RAM unit was still the one with the out of sync LED. So that rules out the software, RAM firmware and
