

YouTube Vanced

YouTube Vanced is a stock Android version of YouTube which includes adblocking and other features. <https://digit.in/dec20-63>

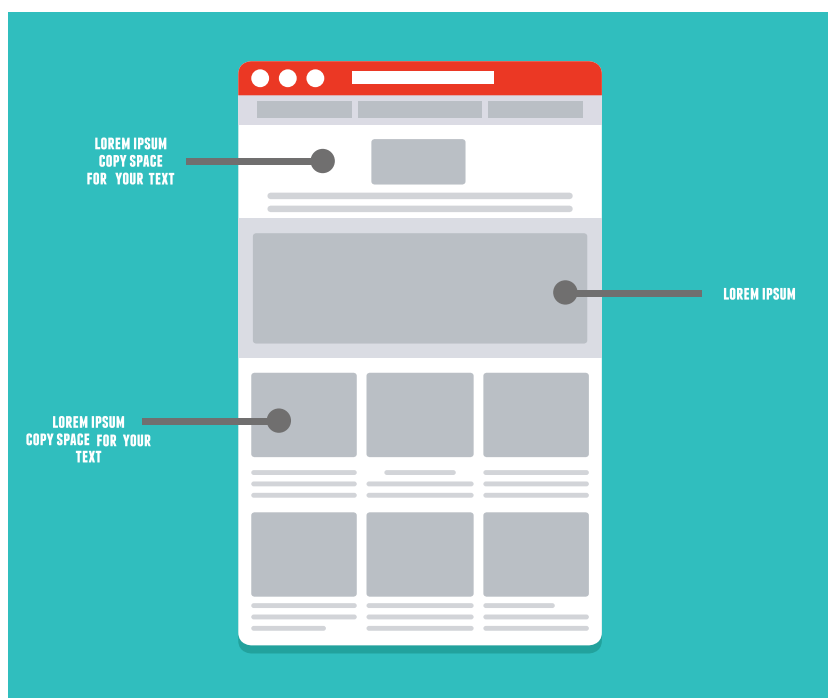

Multiple Implementations

Tutorial on using multiple implementations of an interface in ASP.NET. <https://digit.in/dec20-64>

(Quality Assurance) tests between each update cycle. When building a responsive website, always avoid fixed dimensions and try to use 'ems' for media elements which is a relative unit of measurement. A single 'em' is the size of your current font and 2em means twice the size of your font. So, as the font on the screen scales, so will your media elements. Using fixed dimensions would lead to elements rendering outside your viewport or coming out too small for the screen because every mobile device will have a slightly different viewport. And if you must work with min-width or max-width of the viewport for writing the CSS, stick to one of them and do not mix both.

There are several layout techniques that have proven to be aesthetically-pleasing and functional. You have no doubt seen websites that use elements arranged in a grid-like fashion. Resizing the page leads to resizing of the grid elements to a certain extent before the elements themselves rearrange rather than resizing. CSS Grids are quite popular and other layout methods such as Flexbox work equally well. The good thing about these layout methods are that they reduce the amount of media queries that your browser will make when interacting with your website.

Google has several tools which you can use to identify issues with the working of your website from the perspective of mobile devices. The aptly named 'Mobile-Friendly Test Tool' will examine your website and let you know of any major issues. Similarly, Google's 'PageSpeed Insights Tool' does a thorough analysis of your webpage to provide analysis of several metrics including page load times, individual element load and render times, unused or redundant code elements, server response time, layout shifts, etc. Also, 'PageSpeed Insights' incorporates several important metrics that Google's search engine also looks for while deciding the page rank of a website. 'Web Vitals' is the latest update to Google's

Start off with a good outline of your page

search engine protocol that's set to become active in early 2021. However, the 'PageSpeed Insights Tool' has already started showing results of these metrics so that publishers can start optimising their websites for the same before the Google's Search Engine goes live with the Web Vitals update. As part of PageSpeed, Google also provides several open-source web server modules that publishers can install to optimise their websites.

PAGE STRUCTURE

New websites which have been coded from scratch or themed from the ground up often face this issue. The navigation is often designed from the perspective of the developer and not from the perspective of the user. The developer might have set ideas about the organisational hierarchy of elements on screen. This might not be exactly what the user wants. Let us say you have an ecommerce website that sells books, music, artwork, and movies, among several other product categories. A developer might categorise books, music, artwork, and movies under the same category termed 'multimedia' and be done

with it. Often, in the race to make the UI simple, such inconsiderate groupings do tend to happen. Most users would not look for the word 'multimedia' when hunting for any of the aforementioned things and would probably leave the website without exploring further, which in turn leads to loss in sales. As an ecommerce website, you certainly do not want that happening.

While that takes care of the logic of designing page structure, what is more important is that you also keep in mind the markers that well-established accessibility tools look for when navigating a website. These are termed 'HTML Semantic Elements' and what sets them apart from other elements is that it conveys what the element hosts or is about. <Header> is one such semantic element which indicates the opening section of a website that holds the logo and title of the website along with certain standard web language declarations. <Nav> is another element which holds the navigation elements of the website. Similarly, we have other semantic elements such as <article>, <aside>, <details>, <figcaption>, <figure>, <footer>, <main>, <mark>, <section>,
