

resolve the conflict, which removes the copy shortcut. There is no shortcut for renaming the file or folder set by default in Multi Commander. You can set up such a shortcut to the unmapped F2 key now, by going to the Explorer module, and finding the "rename current file/folder" option.

USE SCRIPTS AND COMMANDS

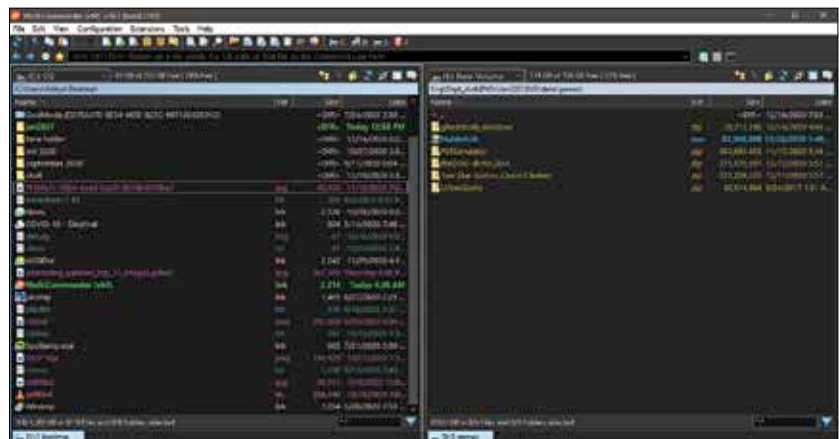

You can use Multi Commander as a control center for your PC, by launching applications from the bottom bar, where the buttons can be customised. There is also a CLI on the top where windows commands can be run. This means you can just type in paint or even explorer here, and the application will fire up, instead of having to invoke the run command. The interface also lets you set up custom commands, for example you can set up a command to run an external application with certain parameters. For example the command, this command quickly starts us up a Quake3 arena server.

```
MC.Run CMD="G:\Quake III
Arena\Quake3.exe" ADMIN +set
dedicated 2 +set net_port
27970 +com_hunkMega 50 +exec
ffa.cfgt
```

Once a command is defined, it can be accessed with a shortcut or even a button. And yes, Multi Commander allows you to add up and customise buttons as well, giving them your icons and letting you decide what they should be doing. You can also change up the buttons of the existing icons if you so desire. The terminal also supports a number of inline commands, that are run by the software itself. For example `mkdir <path>` allows you to rapidly create folders with subfolders. Another command, `dbg fslog` keeps a log of the entire filesystem.

How to remap the shortcuts in Multi Commander

Rule based colouring

COLOUR YOUR FILES!

Rule based file colouring is something that you can use to customise according to your workflow, and is a proxy for tagging the files. If you just want to tag the files then we do have Tagging for Windows also on the DVD. The Multi Commander version is better because you do not have to go with a monolithic file tagging system. Instead, you have a more flexible set of rules that are set within colour profiles. There are three conditions that can be set for each file, all of

which have to be met for the file to appear in a particular colour. The rules can be set based on the names of the files (with support for wildcards), the types of the files, the dates of creation and modification, and even the content of the files. Press the circular colour space button to access the file colouring rules, and set up the profiles. The best thing is that you can set up multiple profiles with different sets of rules for different workflows, and then change the profiles on the fly as and when required. **4**
