

Samsung Balance Mouse

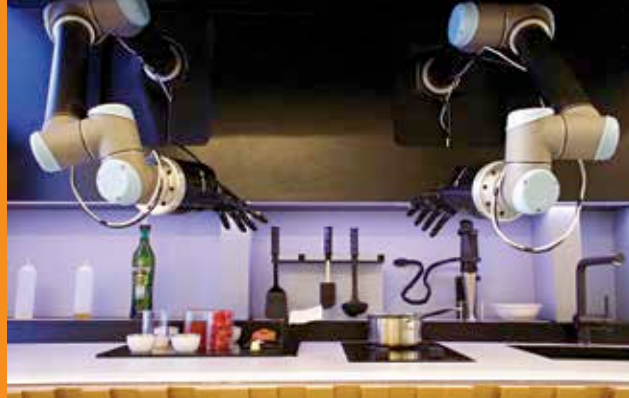

Struggling to find a work-life balance? Especially now when there's no border between work and life, it's easy to get lost in work. Samsung seemingly has a solution to this problem, the Samsung Balance Mouse. Designed alongside advertising agency INNORED and design studio BKID, the Samsung Balance Mouse will literally run away from you if you're working too much.

It appears as a normal wireless mouse at first, but when it's time to ditch the office and head home, the mouse's "ears" shoot up and it runs out of your clutches.

It's definitely a playful gadget, but the issue behind it is quite serious; making this the perfect accessory for the overworked. The mouse is even designed to shed its outer layer should you catch it, revealing a blue-pink core that will also scam away.

The concept mouse was designed as part of a work-life balance campaign in Korea being run by Innored. Unfortunately, the work-life balance mouse isn't an actual product, but we really wish Samsung would actually make one.

Moley Kitchen Robot

We trust robots with a lot of things nowadays, but usually not enough to keep them anywhere near our kitchens. However, a London-based robotics company, Moley Robotics, has created a robot that can supposedly outdo even qualified cooks in the kitchen. Dubbed Moley, the Moley kitchen robot can not only cook something up from scratch, but also clean up after itself. The Moley kitchen robot was created by a Russian mathematician and computer scientist Mark Oleynik in collaboration with Tim Anderson, a well known chef who's known for his culinary innovations and for winning the 2011 BBC MasterChef.

The main goal of the Moley is to be able to create restaurant grade meals without the owner having to lift a single finger. Moley is capable of creating over 30 restaurant grade dishes so far, with more recipes being added every month. While that's all well and good, at a \$331,800 price tag, you might think there are better things to buy, unless you already own a restaurant.

For how it works, Moley is equipped with two "hands" that can fully replicate human movements. This allows it to cook exactly as a human would, without the fumbles.

Canvas automated construction robotic arm

Robotics company Canvas have used machine learning to create a robot arm with sensors which automates the process of installing drywalls. This automated construction robotic arm is supposedly capable of operating faster than a human. Traditionally such machines are rented out or sold, Canvas robots' however, are operated by trained workers from the International Union of Painters and Allied Trades. This makes them more like subcontractors. The number of required workers on site is still significantly reduced, so you can see how this is beneficial under current circumstances. Canvas is currently focusing its robots on learning how to perfectly install drywalls for large commercial sites, i.e., sites larger than 10,000 square

feet. Once they've perfected drywalling, Canvas plans to expand even further in terms of the robotic arms functionalities, by adding the ability to paint, and spray-

on insulation as well. This is in addition to expanding to more locations, as of right now they're only active in the San Francisco Bay Area.
